| 11              | Error code valid (0 = invalid; 1 = valid)                                                                                                                                                                                                                            |
| 12              | NMI unblocking due to IRET                                                                                                                                                                                                                                           |

**Table 21-14. Format of the VM-Exit Interruption-Information Field (Contd.)**

| Bit Position(s) | Content                 |
|-----------------|-------------------------|
| 30:13           | Reserved (cleared to 0) |
| 31              | Valid                   |

- **VM-exit interruption error code** (32 bits). For VM exits caused by hardware exceptions that would have delivered an error code on the stack, this field receives that error code.

Section 24.2.2 provides details of how these fields are saved on VM exits.

### 21.9.3 Information for VM Exits That Occur During Event Delivery

Additional information is provided for VM exits that occur during event delivery in VMX non-root operation.<sup>1</sup> This information is provided in the following fields:

- **IDT-vectoring information** (32 bits). This field receives basic information associated with the event that was being delivered when the VM exit occurred. Table 21-15 describes this field.

**Table 21-15. Format of the IDT-Vectoring Information Field**

| Bit Position(s) | Content                                                                                                                                                                                                                     |
|-----------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7:0             | Vector of interrupt or exception                                                                                                                                                                                            |
| 10:8            | Interruption type:<br>0: External interrupt<br>1: Not used<br>2: Non-maskable interrupt (NMI)<br>3: Hardware exception<br>4: Software interrupt<br>5: Privileged software exception<br>6: Software exception<br>7: Not used |
| 11              | Error code valid (0 = invalid; 1 = valid)                                                                                                                                                                                   |
| 12              | Undefined                                                                                                                                                                                                                   |
| 30:13           | Reserved (cleared to 0)                                                                                                                                                                                                     |
| 31              | Valid                                                                                                                                                                                                                       |

---

1. This includes cases in which the event delivery was caused by event injection as part of VM entry; see Section 23.5.1.2.

- **IDT-vectoring error code** (32 bits). For VM exits that occur during delivery of hardware exceptions that would have delivered an error code on the stack, this field receives that error code.

See Section 24.2.3 provides details of how these fields are saved on VM exits.

#### 21.9.4 Information for VM Exits Due to Instruction Execution

The following fields are used for VM exits caused by attempts to execute certain instructions in VMX non-root operation:

- **VM-exit instruction length** (32 bits). For VM exits resulting from instruction execution, this field receives the length in bytes of the instruction whose execution led to the VM exit.<sup>1</sup> See Section 24.2.4 for details of when and how this field is used.
- **VM-exit instruction information** (32 bits). This field is used for VM exits due to attempts to execute INS, INVEPT, INVPID, LIDT, LGDT, LLDT, LTR, OUTS, SIDT, SGDT, SLDT, STR, VMCLEAR, VMPLRD, VMPLRST, VMREAD, VMWRITE, or VMXON.<sup>2</sup> The format of the field depends on the cause of the VM exit. See Section 24.2.4 for details.

The following fields (64 bits each; 32 bits on processors that do not support Intel 64 architecture) are used only for VM exits due to SMIs that arrive immediately after retirement of I/O instructions. They provide information about that I/O instruction:

- **I/O RCX**. The value of RCX before the I/O instruction started.
- **I/O RSI**. The value of RSI before the I/O instruction started.
- **I/O RDI**. The value of RDI before the I/O instruction started.
- **I/O RIP**. The value of RIP before the I/O instruction started (the RIP that addressed the I/O instruction).

#### 21.9.5 VM-Instruction Error Field

The 32-bit **VM-instruction error field** does not provide information about the most recent VM exit. In fact, it is not modified on VM exits. Instead, it provides information about errors encountered by a non-faulting execution of one of the VMX instructions.

- 
1. This field is also used for VM exits that occur during the delivery of a software interrupt or software exception.
  2. Whether the processor provides this information on VM exits due to attempts to execute INS or OUTS can be determined by consulting the VMX capability MSR IA32\_VMX\_BASIC (see Appendix G.1).

## 21.10 SOFTWARE USE OF THE VMCS AND RELATED STRUCTURES

This section details guidelines that software should observe when using a VMCS and related structures. It also provides descriptions of consequences for failing to follow guidelines.

### 21.10.1 Software Use of Virtual-Machine Control Structures

To ensure proper processor behavior, software should observe certain guidelines when using an active VMCS.

No VMCS should ever be active on more than one logical processor. If a VMCS is to be “migrated” from one logical processor to another, the first logical processor should execute VMCLEAR for the VMCS (to make it inactive on that logical processor and to ensure that all VMCS data are in memory) before the other logical processor executes VMPTRLD for the VMCS (to make it active on the second logical processor). A VMCS that is made active on more than one logical processor may become **corrupted** (see below).

Software should use the VMREAD and VMWRITE instructions to access the different fields in the current VMCS (see Section 21.10.2). Software should never access or modify the VMCS data of an active VMCS using ordinary memory operations, in part because the format used to store the VMCS data is implementation-specific and not architecturally defined, and also because a logical processor may maintain some VMCS data of an active VMCS on the processor and not in the VMCS region. The following items detail some of the hazards of accessing VMCS data using ordinary memory operations:

- Any data read from a VMCS with an ordinary memory read does not reliably reflect the state of the VMCS. Results may vary from time to time or from logical processor to logical processor.
- Writing to a VMCS with an ordinary memory write is not guaranteed to have a deterministic effect on the VMCS. Doing so may cause the VMCS to become corrupted (see below).

(Software can avoid these hazards by removing any linear-address mappings to a VMCS region before executing a VMPTRLD for that region and by not remapping it until after executing VMCLEAR for that region.)

If a logical processor leaves VMX operation, any VMCSs active on that logical processor may be corrupted (see below). To prevent such corruption of a VMCS that may be used either after a return to VMX operation or on another logical processor, software should VMCLEAR that VMCS before executing the VMXOFF instruction or removing power from the processor (e.g., as part of a transition to the S3 and S4 power states).

This section has identified operations that may cause a VMCS to become corrupted. These operations may cause the VMCS’s data to become undefined. Behavior may be

## VIRTUAL-MACHINE CONTROL STRUCTURES

unpredictable if that VMCS used subsequently on any logical processor. The following items detail some hazards of VMCS corruption:

- VM entries may fail for unexplained reasons or may load undesired processor state.
- The processor may not correctly support VMX non-root operation as documented in Chapter 22 and may generate unexpected VM exits.
- VM exits may load undesired processor state, save incorrect state into the VMCS, or cause the logical processor to transition to a shutdown state.

### 21.10.2 VMREAD, VMWRITE, and Encodings of VMCS Fields

Every field of the VMCS is associated with a 32-bit value that is its **encoding**. The encoding is provided in an operand to VMREAD and VMWRITE when software wishes to read or write that field. These instructions fail if given, in 64-bit mode, an operand that sets an encoding bit beyond bit 32. See Chapter 5 of the *Intel® 64 and IA-32 Architectures Software Developer’s Manual, Volume 2B*, for a description of these instructions.

The structure of the 32-bit encodings of the VMCS components is determined principally by the width of the fields and their function in the VMCS. See Table 21-16.

Table 21-16. Structure of VMCS Component Encoding

| Bit Position(s) | Contents                                                                                    |
|-----------------|---------------------------------------------------------------------------------------------|
| 31:15           | Reserved (must be 0)                                                                        |
| 14:13           | Width:<br>0: 16-bit<br>1: 64-bit<br>2: 32-bit<br>3: natural-width                           |
| 12              | Reserved (must be 0)                                                                        |
| 11:10           | Type:<br>0: control<br>1: read-only data<br>2: guest state<br>3: host state                 |
| 9:1             | Index                                                                                       |
| 0               | Access type (0 = full; 1 = high); must be full for 16-bit, 32-bit, and natural-width fields |

The following items detail the meaning of the bits in each encoding:

- **Field width.** Bits 14:13 encode the width of the field.
    - A value of 0 indicates a 16-bit field.
    - A value of 1 indicates a 64-bit field.
    - A value of 2 indicates a 32-bit field.
    - A value of 3 indicates a **natural-width** field. Such fields have 64 bits on processors that support Intel 64 architecture and 32 bits on processors that do not.
- Fields whose encodings use value 1 are specially treated to allow 32-bit software access to all 64 bits of the field. Such access is allowed by defining, for each such field, an encoding that allows direct access to the high 32 bits of the field. See below.
- **Field type.** Bits 11:10 encode the type of VMCS field: control, guest-state, host-state, or read-only data. The last category includes the VM-exit information fields and the VM-instruction error field.
  - **Index.** Bits 9:1 distinguish components with the same field width and type.
  - **Access type.** Bit 0 must be 0 for all fields except for 64-bit fields (those with field-width 1; see above). A VMREAD or VMWRITE using an encoding with this bit cleared to 0 accesses the entire field. For a 64-bit field with field-width 1, a VMREAD or VMWRITE using an encoding with this bit set to 1 accesses only the high 32 bits of the field.

Appendix H gives the encodings of all fields in the VMCS.

The following describes the operation of VMREAD and VMWRITE based on processor mode, VMCS-field width, and access type:

- 16-bit fields:
  - A VMREAD returns the value of the field in bits 15:0 of the destination operand; other bits of the destination operand are cleared to 0.
  - A VMWRITE writes the value of bits 15:0 of the source operand into the VMCS field; other bits of the source operand are not used.
- 32-bit fields:
  - A VMREAD returns the value of the field in bits 31:0 of the destination operand; in 64-bit mode, bits 63:32 of the destination operand are cleared to 0.
  - A VMWRITE writes the value of bits 31:0 of the source operand into the VMCS field; in 64-bit mode, bits 63:32 of the source operand are not used.
- 64-bit fields and natural-width fields using the full access type outside IA-32e mode.
  - A VMREAD returns the value of bits 31:0 of the field in its destination operand; bits 63:32 of the field are ignored.

## VIRTUAL-MACHINE CONTROL STRUCTURES

- A VMWRITE writes the value of its source operand to bits 31:0 of the field and clears bits 63:32 of the field.
- 64-bit fields and natural-width fields using the full access type in 64-bit mode (only on processors that support Intel 64 architecture).
  - A VMREAD returns the value of the field in bits 63:0 of the destination operand
  - A VMWRITE writes the value of bits 63:0 of the source operand into the VMCS field.
- 64-bit fields using the high access type.
  - A VMREAD returns the value of bits 63:32 of the field in bits 31:0 of the destination operand; in 64-bit mode, bits 63:32 of the destination operand are cleared to 0.
  - A VMWRITE writes the value of bits 31:0 of the source operand to bits 63:32 of the field; in 64-bit mode, bits 63:32 of the source operand are not used.

Software seeking to read a 64-bit field outside IA-32e mode can use VMREAD with the full access type (reading bits 31:0 of the field) and VMREAD with the high access type (reading bits 63:32 of the field); the order of the two VMREAD executions is not important. Software seeking to modify a 64-bit field outside IA-32e mode should first use VMWRITE with the full access type (establishing bits 31:0 of the field while clearing bits 63:32) and then use VMWRITE with the high access type (establishing bits 63:32 of the field).

### 21.10.3 Initializing a VMCS

Software should initialize fields in a VMCS (using VMWRITE) before using the VMCS for VM entry. Failure to do so may result in unpredictable behavior; for example, a VM entry may fail for unexplained reasons, or a successful transition (VM entry or VM exit) may load processor state with unexpected values.

It is not necessary to initialize fields that the logical processor will not use. (For example, it is not necessary to unitize the MSR-bitmap address if the “use MSR bitmaps” VM-execution control is 0.)

A processor maintains some VMCS information that cannot be modified with the VMWRITE instruction; this includes a VMCS’s launch state (see Section 21.1). Such information may be stored in the VMCS data portion of a VMCS region. Because the format of this information is implementation-specific, there is no way for software to know, when it first allocates a region of memory for use as a VMCS region, how the processor will determine this information from the contents of the memory region.

In addition to its other functions, the VMCLEAR instruction initializes any implementation-specific information in the VMCS region referenced by its operand. To avoid the uncertainties of implementation-specific behavior, software should execute VMCLEAR on a VMCS region before making the corresponding VMCS active with

VMPTRLD for the first time. (Figure 21-1 illustrates how execution of VMCLEAR puts a VMCS into a well-defined state.)

The following software usage is consistent with these limitations:

- VMCLEAR should be executed for a VMCS before it is used for VM entry for the first time.
- VMLAUNCH should be used for the first VM entry using a VMCS after VMCLEAR has been executed for that VMCS.
- VMRESUME should be used for any subsequent VM entry using a VMCS (until the next execution of VMCLEAR for the VMCS).

It is expected that, in general, VMRESUME will have lower latency than VMLAUNCH. Since “migrating” a VMCS from one logical processor to another requires use of VMCLEAR (see Section 21.10.1), which sets the launch state of the VMCS to “clear”, such migration requires the next VM entry to be performed using VMLAUNCH. Software developers can avoid the performance cost of increased VM-entry latency by avoiding unnecessary migration of a VMCS from one logical processor to another.

#### 21.10.4 Software Access to Related Structures

In addition to data in the VMCS region itself, VMX non-root operation can be controlled by data structures that are referenced by pointers in a VMCS (for example, the I/O bitmaps). While the pointers to these data structures are parts of the VMCS, the data structures themselves are not. They are not accessible using VMREAD and VMWRITE but by ordinary memory writes.

Software should ensure that each such data structure is modified only when no logical processor with a current VMCS that references it is in VMX non-root operation. Doing otherwise may lead to unpredictable behavior (including behaviors identified in Section 21.10.1).

#### 21.10.5 VMXON Region

Before executing VMXON, software allocates a region of memory (called the VMXON region)<sup>1</sup> that the logical processor uses to support VMX operation. The physical address of this region (the VMXON pointer) is provided in an operand to VMXON. The VMXON pointer is subject to the limitations that apply to VMCS pointers:

- The VMXON pointer must be 4-KByte aligned (bits 11:0 must be zero).
- The VMXON pointer must not set any bits beyond the processor’s physical-address width.<sup>2,3</sup>

---

1. The amount of memory required for the VMXON region is the same as that required for a VMCS region. This size is implementation specific and can be determined by consulting the VMX capability MSR IA32\_VMX\_BASIC (see Appendix G.1).

## VIRTUAL-MACHINE CONTROL STRUCTURES

Before executing VMXON, software should write the VMCS revision identifier (see Section 21.2) to the VMXON region. It need not initialize the VMXON region in any other way. Software should use a separate region for each logical processor and should not access or modify the VMXON region of a logical processor between execution of VMXON and VMXOFF on that logical processor. Doing otherwise may lead to unpredictable behavior (including behaviors identified in Section 21.10.1).

- 
2. Software can determine a processor's physical-address width by executing CPUID with 80000008H in EAX. The physical-address width is returned in bits 7:0 of EAX.
  3. If IA32\_VMX\_BASIC[48] is read as 1, the VMXON pointer must not set any bits in the range 63:32; see Appendix G.1.

## CHAPTER 22

# VMX NON-ROOT OPERATION

---

In a virtualized environment using VMX, the guest software stack typically runs on a logical processor in VMX non-root operation. This mode of operation is similar to that of ordinary processor operation outside of the virtualized environment. This chapter describes the differences between VMX non-root operation and ordinary processor operation with special attention to causes of VM exits (which bring a logical processor from VMX non-root operation to root operation). The differences between VMX non-root operation and ordinary processor operation are described in the following sections:

- Section 22.1, “Instructions That Cause VM Exits”
- Section 22.2, “APIC-Access VM Exits”
- Section 22.3, “Other Causes of VM Exits”
- Section 22.4, “Changes to Instruction Behavior in VMX Non-Root Operation”
- Section 22.5, “APIC Accesses That Do Not Cause VM Exits”
- Section 22.6, “Other Changes in VMX Non-Root Operation”
- Section 22.7, “Features Specific to VMX Non-Root Operation”

Chapter 21, “Virtual-Machine Control Structures,” describes the data control structure that governs VMX operation (root and non-root). Chapter 22, “VMX Non-Root Operation,” describes the operation of VM entries which allow the processor to transition from VMX root operation to non-root operation.

### 22.1 INSTRUCTIONS THAT CAUSE VM EXITS

Certain instructions may cause VM exits if executed in VMX non-root operation. Unless otherwise specified, such VM exits are “fault-like,” meaning that the instruction causing the VM exit does not execute and no processor state is updated by the instruction. Section 24.1 details architectural state in the context of a VM exit.

Section 22.1.1 defines the prioritization between faults and VM exits for instructions subject to both. Section 22.1.2 identifies instructions that cause VM exits whenever they are executed in VMX non-root operation (and thus can never be executed in VMX non-root operation). Section 22.1.3 identifies instructions that cause VM exits depending on the settings of certain VM-execution control fields (see Section 21.6).

#### 22.1.1 Relative Priority of Faults and VM Exits

The following principles describe the ordering between existing faults and VM exits:

## VMX NON-ROOT OPERATION

- Certain exceptions have priority over VM exits. These include invalid-opcode exceptions, faults based on privilege level,<sup>1</sup> and general-protection exceptions that are based on checking I/O permission bits in the task-state segment (TSS). For example, execution of RDMSR with CPL = 3 generates a general-protection exception and not a VM exit.<sup>2</sup>
- Faults incurred while fetching instruction operands have priority over VM exits that are conditioned based on the contents of those operands (see LMSW in Section 22.1.3).
- VM exits caused by execution of the INS and OUTS instructions (resulting either because the “unconditional I/O exiting” VM-execution control is 1 or because the “use I/O bitmaps control is 1) have priority over the following faults:
  - A general-protection fault due to the relevant segment (ES for INS; DS for OUTS unless overridden by an instruction prefix) being unusable
  - A general-protection fault due to an offset beyond the limit of the relevant segment
  - An alignment-check exception
- Fault-like VM exits have priority over exceptions other than those mentioned above. For example, RDMSR of a non-existent MSR with CPL = 0 generates a VM exit and not a general-protection exception.

When Section 22.1.2 or Section 22.1.3 (below) identify an instruction execution that may lead to a VM exit, it is assumed that the instruction does not incur a fault that takes priority over a VM exit.

### 22.1.2 Instructions That Cause VM Exits Unconditionally

The following instructions cause VM exits when they are executed in VMX non-root operation: CPUID, GETSEC,<sup>3</sup> INVD, and XSETBV.<sup>4</sup> This is also true of instructions introduced with VMX, which include: INVEPT, INVPVID, VMCALL,<sup>5</sup> VMCLEAR, VMLAUNCH, VMPTRLD, VMPTRST, VMREAD, VMRESUME, VMWRITE, VMXOFF, and VMXON.

- 
1. These include faults generated by attempts to execute, in virtual-8086 mode, privileged instructions that are not recognized in that mode.
  2. MOV DR is an exception to this rule; see Section 22.1.3.
  3. An execution of GETSEC in VMX non-root operation causes a VM exit if CR4.SMXE[Bit 14] = 1 regardless of the value of CPL or RAX. An execution of GETSEC causes an invalid-opcode exception (#UD) if CR4.SMXE[Bit 14] = 0.
  4. An execution of XSETBV in VMX non-root operation causes a VM exit if CR4.OSXSAVE[Bit 18] = 1 regardless of the value of CPL, RAX, RCX, or RDX. An execution of XSETBV causes an invalid-opcode exception (#UD) if CR4.OSXSAVE[Bit 18] = 0.
  5. Under the dual-monitor treatment of SMIs and SMM, executions of VMCALL cause SMM VM exits in VMX root operation outside SMM. See Section 26.15.2.

### 22.1.3 Instructions That Cause VM Exits Conditionally

Certain instructions cause VM exits in VMX non-root operation depending on the setting of the VM-execution controls. The following instructions can cause “fault-like” VM exits based on the conditions described:

- **CLTS.** The CLTS instruction causes a VM exit if the bits in position 3 (corresponding to CRO.TS) are set in both the CRO guest/host mask and the CRO read shadow.
- **HLT.** The HLT instruction causes a VM exit if the “HLT exiting” VM-execution control is 1.
- **IN, INS/INSB/INSW/INSD, OUT, OUTS/OUTSB/OUTSW/OUTSD.** The behavior of each of these instructions is determined by the settings of the “unconditional I/O exiting” and “use I/O bitmaps” VM-execution controls:
  - If both controls are 0, the instruction executes normally.
  - If the “unconditional I/O exiting” VM-execution control is 1 and the “use I/O bitmaps” VM-execution control is 0, the instruction causes a VM exit.
  - If the “use I/O bitmaps” VM-execution control is 1, the instruction causes a VM exit if it attempts to access an I/O port corresponding to a bit set to 1 in the appropriate I/O bitmap (see Section 21.6.4). If an I/O operation “wraps around” the 16-bit I/O-port space (accesses ports FFFFH and 0000H), the I/O instruction causes a VM exit (the “unconditional I/O exiting” VM-execution control is ignored if the “use I/O bitmaps” VM-execution control is 1).

See Section 22.1.1 for information regarding the priority of VM exits relative to faults that may be caused by the INS and OUTS instructions.

- **INVLPG.** The INVLPG instruction causes a VM exit if the “INVLPG exiting” VM-execution control is 1.
- **LGDT, LIDT, LLDT, LTR, SGDT, SIDT, SLDT, STR.** These instructions cause VM exits if the “descriptor-table exiting” VM-execution control is 1.<sup>1</sup>
- **LMSW.** In general, the LMSW instruction causes a VM exit if it would write, for any bit set in the low 4 bits of the CRO guest/host mask, a value different than the corresponding bit in the CRO read shadow. LMSW never clears bit 0 of CRO (CRO.PE); thus, LMSW causes a VM exit if either of the following are true:
  - The bits in position 0 (corresponding to CRO.PE) are set in both the CRO guest/mask and the source operand, and the bit in position 0 is clear in the CRO read shadow.
  - For any bit position in the range 3:1, the bit in that position is set in the CRO guest/mask and the values of the corresponding bits in the source operand and the CRO read shadow differ.

---

1. “Descriptor-table exiting” is a secondary processor-based VM-execution control. If bit 31 of the primary processor-based VM-execution controls is 0, VMX non-root operation functions as if the “descriptor-table exiting” VM-execution control were 0. See Section 21.6.2.

## VMX NON-ROOT OPERATION

- **MONITOR.** The MONITOR instruction causes a VM exit if the “MONITOR exiting” VM-execution control is 1.
- **MOV from CR3.** The MOV from CR3 instruction causes a VM exit if the “CR3-store exiting” VM-execution control is 1. The first processors to support the virtual-machine extensions supported only the 1-setting of this control.
- **MOV from CR8.** The MOV from CR8 instruction (which can be executed only in 64-bit mode) causes a VM exit if the “CR8-store exiting” VM-execution control is 1. If this control is 0, the behavior of the MOV from CR8 instruction is modified if the “use TPR shadow” VM-execution control is 1 (see Section 22.4).
- **MOV to CRO.** The MOV to CRO instruction causes a VM exit unless the value of its source operand matches, for the position of each bit set in the CRO guest/host mask, the corresponding bit in the CRO read shadow. (If every bit is clear in the CRO guest/host mask, MOV to CRO cannot cause a VM exit.)
- **MOV to CR3.** The MOV to CR3 instruction causes a VM exit unless the “CR3-load exiting” VM-execution control is 0 or the value of its source operand is equal to one of the CR3-target values specified in the VMCS. If the CR3-target count in  $n$ , only the first  $n$  CR3-target values are considered; if the CR3-target count is 0, MOV to CR3 always causes a VM exit.

The first processors to support the virtual-machine extensions supported only the 1-setting of the “CR3-load exiting” VM-execution control. These processors always consult the CR3-target controls to determine whether an execution of MOV to CR3 causes a VM exit.

- **MOV to CR4.** The MOV to CR4 instruction causes a VM exit unless the value of its source operand matches, for the position of each bit set in the CR4 guest/host mask, the corresponding bit in the CR4 read shadow.
- **MOV to CR8.** The MOV to CR8 instruction (which can be executed only in 64-bit mode) causes a VM exit if the “CR8-load exiting” VM-execution control is 1. If this control is 0, the behavior of the MOV to CR8 instruction is modified if the “use TPR shadow” VM-execution control is 1 (see Section 22.4) and it may cause a trap-like VM exit (see below).
- **MOV DR.** The MOV DR instruction causes a VM exit if the “MOV-DR exiting” VM-execution control is 1. Such VM exits represent an exception to the principles identified in Section 22.1.1 in that they take priority over the following: general-protection exceptions based on privilege level; and invalid-opcode exceptions that occur because CR4.DE=1 and the instruction specified access to DR4 or DR5.
- **MWAIT.** The MWAIT instruction causes a VM exit if the “MWAIT exiting” VM-execution control is 1. If this control is 0, the behavior of the MWAIT instruction may be modified (see Section 22.4).
- **PAUSE.** The behavior of each of this instruction depends on CPL and the settings of the “PAUSE exiting” and “PAUSE-loop exiting” VM-execution controls:
  - CPL = 0.
    - If the “PAUSE exiting” and “PAUSE-loop exiting” VM-execution controls are both 0, the PAUSE instruction executes normally.

- If the “PAUSE exiting” VM-execution control is 1, the PAUSE instruction causes a VM exit (the “PAUSE-loop exiting” VM-execution control is ignored if CPL = 0 and the “PAUSE exiting” VM-execution control is 1).
- If the “PAUSE exiting” VM-execution control is 0 and the “PAUSE-loop exiting” VM-execution control is 1, the following treatment applies.

The logical processor determines the amount of time between this execution of PAUSE and the previous execution of PAUSE at CPL 0. If this amount of time exceeds the value of the VM-execution control field PLE\_Gap, the processor considers this execution to be the first execution of PAUSE in a loop. (It also does so for the first execution of PAUSE at CPL 0 after VM entry.)

Otherwise, the logical processor determines the amount of time since the most recent execution of PAUSE that was considered to be the first in a loop. If this amount of time exceeds the value of the VM-execution control field PLE\_Window, a VM exit occurs.

For purposes of these computations, time is measured based on a counter that runs at the same rate as the timestamp counter (TSC).

- CPL > 0.

- If the “PAUSE exiting” VM-execution control is 0, the PAUSE instruction executes normally.
- If the “PAUSE exiting” VM-execution control is 1, the PAUSE instruction causes a VM exit.

The “PAUSE-loop exiting” VM-execution control is ignored if CPL > 0.

- **RDMSR.** The RDMSR instruction causes a VM exit if any of the following are true:
  - The “use MSR bitmaps” VM-execution control is 0.
  - The value of ECX is not in the range 00000000H – 00001FFFH or C0000000H – C0001FFFH.
  - The value of ECX is in the range 00000000H – 00001FFFH and bit *n* in read bitmap for low MSRs is 1, where *n* is the value of ECX.
  - The value of ECX is in the range C0000000H – C0001FFFH and bit *n* in read bitmap for high MSRs is 1, where *n* is the value of ECX & 00001FFFH.

See Section 21.6.9 for details regarding how these bitmaps are identified.

- **RDPMC.** The RDPMC instruction causes a VM exit if the “RDPMC exiting” VM-execution control is 1.
- **RDTSC.** The RDTSC instruction causes a VM exit if the “RDTSC exiting” VM-execution control is 1.
- **RDTSCP.** The RDTSCP instruction causes a VM exit if the “RDTSC exiting” and “enable RDTSCP” VM-execution controls are both 1.
- **RSM.** The RSM instruction causes a VM exit if executed in system-management mode (SMM).<sup>1</sup>

## VMX NON-ROOT OPERATION

- **WBINVD.** The WBINVD instruction causes a VM exit if the “WBINVD exiting” VM-execution control is 1.<sup>1</sup>
- **WRMSR.** The WRMSR instruction causes a VM exit if any of the following are true:
  - The “use MSR bitmaps” VM-execution control is 0.
  - The value of ECX is not in the range 00000000H – 00001FFFH or C000000H – C0001FFFH.
  - The value of ECX is in the range 0000000H – 00001FFFH and bit *n* in write bitmap for low MSRs is 1, where *n* is the value of ECX.
  - The value of ECX is in the range C000000H – C0001FFFH and bit *n* in write bitmap for high MSRs is 1, where *n* is the value of ECX & 00001FFFH.

See Section 21.6.9 for details regarding how these bitmaps are identified.

If an execution of WRMSR does not cause a VM exit as specified above and ECX = 808H (indicating the TPR MSR), instruction behavior is modified if the “virtualize x2APIC mode” VM-execution control is 1 (see Section 22.4) and it may cause a trap-like VM exit (see below).<sup>2</sup>

The MOV to CR8 and WRMSR instructions may cause “trap-like” VM exits. In such a case, the instruction completes before the VM exit occurs and that processor state is updated by the instruction (for example, the value of CS:RIP saved in the guest-state area of the VMCS references the next instruction).

Specifically, a trap-like VM exit occurs following either instruction if the execution reduces the value of the TPR shadow below that of the TPR threshold VM-execution control field (see Section 21.6.8 and Section 22.4) and the following hold:

- For MOV to CR8:
  - The “CR8-load exiting” VM-execution control is 0.
  - The “use TPR shadow” VM-execution control is 1.
- For WRMSR:
  - The “use MSR bitmaps” VM-execution control is 1, the value of ECX is 808H, and bit 808H in write bitmap for low MSRs is 0 (see above).
  - The “virtualize x2APIC mode” VM-execution control is 1.

- 
1. Execution of the RSM instruction outside SMM causes an invalid-opcode exception regardless of whether the processor is in VMX operation. It also does so in VMX root operation in SMM; see Section 26.15.3.
  1. “WBINVD exiting” is a secondary processor-based VM-execution control. If bit 31 of the primary processor-based VM-execution controls is 0, VMX non-root operation functions as if the “WBINVD exiting” VM-execution control were 0. See Section 21.6.2.
  2. “Virtualize x2APIC mode” is a secondary processor-based VM-execution control. If bit 31 of the primary processor-based VM-execution controls is 0, VMX non-root operation functions as if the “virtualize x2APIC mode” VM-execution control were 0. See Section 21.6.2.

## 22.2 APIC-ACCESS VM EXITS

If the “virtualize APIC accesses” VM-execution control is 1, an attempt to access memory using a physical address on the APIC-access page (see Section 21.6.8) causes a VM exit.<sup>1,2</sup> Such a VM exit is called an **APIC-access VM exit**.

Whether an operation that attempts to access memory with a physical address on the APIC-access page causes an APIC-access VM exit may be qualified based on the type of access. Section 22.2.1 describes the treatment of linear accesses, while Section 22.2.3 describes that of physical accesses. Section 22.2.4 discusses accesses to the TPR field on the APIC-access page (called VTPR accesses), which do not, if the “use TPR shadow” VM-execution control is 1, cause APIC-access VM exits.

### 22.2.1 Linear Accesses to the APIC-Access Page

An access to the APIC-access page is called a **linear access** if (1) it results from a memory access using a linear address; and (2) the access’s physical address is the translation of that linear address. Section 22.2.1.1 specifies which linear accesses to the APIC-access page cause APIC-access VM exits.

In general, the treatment of APIC-access VM exits caused by linear accesses is similar to that of page faults and EPT violations. Based upon this treatment, Section 22.2.1.2 specifies the priority of such VM exits with respect to other events, while Section 22.2.1.3 discusses instructions that may cause page faults without accessing memory and the treatment when they access the APIC-access page.

#### 22.2.1.1 Linear Accesses That Cause APIC-Access VM Exits

Whether a linear access to the APIC-access page causes an APIC-access VM exit depends in part of the nature of the translation used by the linear address:

- If the linear access uses a translation with a 4-KByte page, it causes an APIC-access VM exit.
- If the linear access uses a translation with a large page (2-MByte, 4-MByte, or 1-GByte), the access may or may not cause an APIC-access VM exit. Section 22.5.1 describes the treatment of such accesses that do not cause an APIC-access VM exits.

- 
1. “Virtualize APIC accesses” is a secondary processor-based VM-execution control. If bit 31 of the primary processor-based VM-execution controls is 0, VMX non-root operation functions as if the “virtualize APIC accesses” VM-execution control were 0. See Section 21.6.2.
  2. Even when addresses are translated using EPT (see Section 25.2), the determination of whether an APIC-access VM exit occurs depends on an access’s physical address, not its guest-physical address.

## VMX NON-ROOT OPERATION

If CR0.PG = 1 and EPT is in use (the “enable EPT” VM-execution control is 1), a linear access uses a translation with a large page only if a large page is specified by both the guest paging structures and the EPT paging structures.<sup>1</sup>

It is recommended that software configure the paging structures so that any translation to the APIC-access page uses a 4-KByte page.

A linear access to the APIC-access page might not cause an APIC-access VM exit if the “enable EPT” VM-execution control is 1 and software has not properly invalidated information cached from the EPT paging structures:

- At time  $t_1$ , EPT was in use, the EPTP value was X, and some guest-physical address Y translated to an address that was not on the APIC-access page at that time. (This might be because the “virtualize APIC accesses” VM-execution control was 0.)
- At later time  $t_2$ , EPT is in use, the EPTP value is X, and a memory access uses a linear address that translates to Y, which now translates to an address on the APIC-access page. (This implies that the “virtualize APIC accesses” VM-execution control is 1 at this time.)
- Software did not execute the INVEPT instruction between times  $t_1$  and  $t_2$ , either with the all-context INVEPT type or with the single-context INVEPT type and X as the INVEPT descriptor.

In this case, the linear access at time  $t_2$  might or might not cause an APIC-access VM exit. If it does not, the access operates on memory on the APIC-access page.

Software can avoid this situation through appropriate use of the INVEPT instruction; see Section 25.3.3.4.

A linear access to the APIC-access page might not cause an APIC-access VM exit if the “enable VPID” VM-execution control is 1 and software has not properly invalidated the TLBs and paging-structure caches:

- At time  $t_1$ , the processor was in VMX non-root operation with non-zero VPID X, and some linear address Y translated to an address that was not on the APIC-access page at that time. (This might be because the “virtualize APIC accesses” VM-execution control was 0.)
- At later time  $t_2$ , the processor was again in VMX non-root operation with VPID X, and a memory access uses linear address, which now translates to an address on the APIC-access page. (This implies that the “virtualize APIC accesses” VM-execution control is 1 at this time.)
- Software did not execute the INVVPID instruction in any of the following ways between times  $t_1$  and  $t_2$ :

---

1. If the capability MSR IA32\_VMX\_CRO\_FIXED0 reports that CR0.PG must be 1 in VMX operation, CR0.PG must be 1 unless the “unrestricted guest” VM-execution control and bit 31 of the primary processor-based VM-execution controls are both 1. “Enable EPT” is a secondary processor-based VM-execution control. If bit 31 of the primary processor-based VM-execution controls is 0, VMX non-root operation functions as if the “enable EPT” VM-execution control were 0. See Section 21.6.2.

- With the individual-address INVPID type and an INVPID descriptor specifying VPID X and linear address Y.
- With the single-context INVPID type and an INVPID descriptor specifying VPID X.
- With the all-context INVEPT type.
- With the single-context-retaining-globals INVPID type and an INVPID descriptor specifying VPID X (assuming that, at time  $t_1$ , the translation for Y was global; see Section 4.10, “Caching Translation Information” in *Intel® 64 and IA-32 Architectures Software Developer’s Manual, Volume 3A* for details regarding global translations).

In this case, the linear access at time  $t_2$  might or might not cause an APIC-access VM exit. If it does not, the access operates on memory on the APIC-access page.

Software can avoid this situation through appropriate use of the INVPID instruction; see Section 25.3.3.3.

### 22.2.1.2 Priority of APIC-Access VM Exits Caused by Linear Accesses

The following items specify the priority relative to other events of APIC-access VM exits caused by linear accesses.

- The priority of an APIC-access VM exit on a linear access to memory is below that of any page fault or EPT violation that that access may incur. That is, a linear access does not cause an APIC-access VM exit if it would cause a page fault or an EPT violation.
- A linear access does not cause an APIC-access VM exit until after the accessed bits are set in the paging structures.
- A linear write access will not cause an APIC-access VM exit until after the dirty bit is set in the appropriate paging structure.
- With respect to all other events, any APIC-access VM exit due to a linear access has the same priority as any page fault or EPT violation that the linear access could cause. (This item applies to other events that the linear access may generate as well as events that may be generated by other accesses by the same instruction or operation.)

These principles imply among other things, that an APIC-access VM exit may occur during the execution of a repeated string instruction (including INS and OUTS). Suppose, for example, that the first  $n$  iterations ( $n$  may be 0) of such an instruction do not access the APIC-access page and that the next iteration does access that page. As a result, the first  $n$  iterations may complete and be followed by an APIC-access VM exit. The instruction pointer saved in the VMCS references the repeated string instruction and the values of the general-purpose registers reflect the completion of  $n$  iterations.

### 22.2.1.3 Instructions That May Cause Page Faults or EPT Violations Without Accessing Memory

APIC-access VM exits may occur as a result of executing an instruction that can cause a page fault or an EPT violation even if that instruction would not access the APIC-access page. The following are some examples:

- The CLFLUSH instruction is considered to read from the linear address in its source operand. If that address translates to one on the APIC-access page, the instruction causes an APIC-access VM exit.
- The ENTER instruction causes a page fault if the byte referenced by the final value of the stack pointer is not writable (even though ENTER does not write to that byte if its size operand is non-zero). If that byte is writable but is on the APIC-access page, ENTER causes an APIC-access VM exit.<sup>1</sup>
- An execution of the MASKMOVQ or MASKMOVDQU instructions with a zero mask may or may not cause a page fault or an EPT violation if the destination page is unwritable (the behavior is implementation-specific). An execution with a zero mask causes an APIC-access VM exit only on processors for which it could cause a page fault or an EPT violation.
- The MONITOR instruction is considered to read from the effective address in RAX. If the linear address corresponding to that address translates to one on the APIC-access page, the instruction causes an APIC-access VM exit.<sup>2</sup>
- An execution of the PREFETCH instruction that would result in an access to the APIC-access page does not cause an APIC-access VM exit.

### 22.2.2 Guest-Physical Accesses to the APIC-Access Page

An access to the APIC-access page is called a **guest-physical access** if (1) CRO.PG = 1;<sup>3</sup> (2) the “enable EPT” VM-execution control is 1;<sup>4</sup> (3) the access’s physical address is the result of an EPT translation; and (4) either (a) the access was

1. The ENTER instruction may also cause page faults due to the memory accesses that it actually does perform. With regard to APIC-access VM exits, these are treated just as accesses by any other instruction.
2. This chapter uses the notation RAX, RIP, RSP, RFLAGS, etc. for processor registers because most processors that support VMX operation also support Intel 64 architecture. For IA-32 processors, this notation refers to the 32-bit forms of those registers (EAX, EIP, ESP, EFLAGS, etc.). In a few places, notation such as EAX is used to refer specifically to lower 32 bits of the indicated register.
3. If the capability MSR IA32\_VMX\_CRO\_FIXED0 reports that CRO.PG must be 1 in VMX operation, CRO.PG must be 1 unless the “unrestricted guest” VM-execution control and bit 31 of the primary processor-based VM-execution controls are both 1.
4. “Enable EPT” is a secondary processor-based VM-execution control. If bit 31 of the primary processor-based VM-execution controls is 0, VMX non-root operation functions as if the “enable EPT” VM-execution control were 0. See Section 21.6.2.

not generated by a linear address; or (b) the access's guest-physical address is not the translation of the access's linear address. Guest-physical accesses include the following when guest-physical addresses are being translated using EPT:

- Reads from the guest paging structures when translating a linear address (such an access uses a guest-physical address that is not the translation of that linear address).
- Loads of the page-directory-pointer-table entries by MOV to CR when the logical processor is using (or that causes the logical processor to use) PAE paging.<sup>1</sup>
- Updates to the accessed and dirty bits in the guest paging structures when using a linear address (such an access uses a guest-physical address that is not the translation of that linear address).

Section 22.2.2.1 specifies when guest-physical accesses to the APIC-access page might not cause APIC-access VM exits. In general, the treatment of APIC-access VM exits caused by guest-physical accesses is similar to that of EPT violations. Based upon this treatment, Section 22.2.2.2 specifies the priority of such VM exits with respect to other events.

### 22.2.2.1 Guest-Physical Accesses That Might Not Cause APIC-Access VM Exits

Whether a guest-physical access to the APIC-access page causes an APIC-access VM exit depends on the nature of the EPT translation used by the guest-physical address and on how software is managing information cached from the EPT paging structures. The following items detail cases in which a guest-physical access to the APIC-access page might not cause an APIC-access VM exit:

- If the access uses a guest-physical address whose translation to the APIC-access page uses an EPT PDPTE that maps a 1-GByte page (because bit 7 of the EPT PDPTE is 1).
- If the access uses a guest-physical address whose translation to the APIC-access page uses an EPT PDE that maps a 2-MByte page (because bit 7 of the EPT PDE is 1).
- Software has not properly invalidated information cached from the EPT paging structures:
  - At time  $t_1$ , EPT was in use, the EPTP value was X, and some guest-physical address Y translated to an address that was not on the APIC-access page at that time. (This might be because the "virtualize APIC accesses" VM-execution control was 0.)
  - At later time  $t_2$ , the EPTP value is X and a memory access uses guest-physical address Y, which now translates to an address on the APIC-access page. (This

---

1. A logical processor uses PAE paging if CRO.PG = 1, CR4.PAE = 1 and IA32\_EFER.LMA = 0. See Section 4.4 in the *Intel® 64 and IA-32 Architectures Software Developer's Manual, Volume 3A*.

## VMX NON-ROOT OPERATION

implies that the “virtualize APIC accesses” VM-execution control is 1 at this time.)

- Software did not execute the INVEPT instruction, either with the all-context INVEPT type or with the single-context INVEPT type and X as the INVEPT descriptor, between times  $t_1$  and  $t_2$ .

In any of the above cases, the guest-physical access at time  $t_2$  might or might not an APIC-access VM exit. If it does not, the access operates on memory on the APIC-access page.

Software can avoid this situation through appropriate use of the INVEPT instruction; see Section 25.3.3.4.

### 22.2.2.2 Priority of APIC-Access VM Exits Caused by Guest-Physical Accesses

The following items specify the priority relative to other events of APIC-access VM exits caused by guest-physical accesses.

- The priority of an APIC-access VM exit caused by a guest-physical access to memory is below that of any EPT violation that that access may incur. That is, a guest-physical access does not cause an APIC-access VM exit if it would cause an EPT violation.
- With respect to all other events, any APIC-access VM exit caused by a guest-physical access has the same priority as any EPT violation that the guest-physical access could cause.

### 22.2.3 Physical Accesses to the APIC-Access Page

An access to the APIC-access page is called a **physical access** if (1) either (a) the “enable EPT” VM-execution control is 0;<sup>1</sup> or (b) the access’s physical address is not the result of a translation through the EPT paging structures; and (2) either (a) the access is not generated by a linear address; or (b) the access’s physical address is not the translation of its linear address.

Physical accesses include the following:

- If the “enable EPT” VM-execution control is 0:
  - Reads from the paging structures when translating a linear address.
  - Loads of the page-directory-pointer-table entries by MOV to CR when the logical processor is using (or that causes the logical processor to use) PAE paging.<sup>2</sup>

---

1. “Enable EPT” is a secondary processor-based VM-execution control. If bit 31 of the primary processor-based VM-execution controls is 0, VMX non-root operation functions as if the “enable EPT” VM-execution control were 0. See Section 21.6.2.

- Updates to the accessed and dirty bits in the paging structures.
- If the “enable EPT” VM-execution control is 1, accesses to the EPT paging structures.
- Any of the following accesses made by the processor to support VMX non-root operation:
  - Accesses to the VMCS region.
  - Accesses to data structures referenced (directly or indirectly) by physical addresses in VM-execution control fields in the VMCS. These include the I/O bitmaps, the MSR bitmaps, and the virtual-APIC page.
- Accesses that effect transitions into and out of SMM.<sup>1</sup> These include the following:
  - Accesses to SMRAM during SMI delivery and during execution of RSM.
  - Accesses during SMM VM exits (including accesses to MSEG) and during VM entries that return from SMM.

A physical access to the APIC-access page may or may not cause an APIC-access VM exit. (A physical write to the APIC-access page may write to memory as specified in Section 22.5.2 before causing the APIC-access VM exit.) The priority of an APIC-access VM exit caused by physical access is not defined relative to other events that the access may cause. Section 22.5.2 describes the treatment of physical accesses to the APIC-access page that do not cause APIC-access VM exits.

It is recommended that software not set the APIC-access address to any of those used by physical memory accesses (identified above). For example, it should not set the APIC-access address to the physical address of any of the active paging structures if the “enable EPT” VM-execution control is 0.

#### 22.2.4 VTPR Accesses

A memory access is a **VTPR access** if all of the following hold: (1) the “use TPR shadow” VM-execution control is 1; (2) the access is not for an instruction fetch; (3) the access is at most 32 bits in width; and (4) the access is to offset 80H on the APIC-access page.

A memory access is not a VTPR access (even if it accesses only bytes in the range 80H-83H on the APIC-access page) if any of the following hold: (1) the “use TPR shadow” VM-execution control is 0; (2) the access is for an instruction fetch; (3) the access is more than 32 bits in width; or (4) the access is to some offset is on the APIC-access page other than 80H. For example, a 16-bit access to offset 81H on the

- 
- 2. A logical processor uses PAE paging if CRO.PG = 1, CR4.PAE = 1 and IA32\_EFER.LMA = 0. See Section 4.4 in the *Intel® 64 and IA-32 Architectures Software Developer’s Manual, Volume 3A*.
  - 1. Technically, these accesses do not occur in VMX non-root operation. They are included here for clarity.

## VMX NON-ROOT OPERATION

APIC-access page is **not** a VTPR access, even if the “use TPR shadow” VM-execution control is 1.

In general, VTPR accesses do not cause APIC-access VM exits. Instead, they are treated as described in Section 22.5.3. Physical VTPR accesses (see Section 22.2.3) may or may not cause APIC-access VM exits; see Section 22.5.2.

## 22.3 OTHER CAUSES OF VM EXITS

In addition to VM exits caused by instruction execution, the following events can cause VM exits:

- **Exceptions.** Exceptions (faults, traps, and aborts) cause VM exits based on the exception bitmap (see Section 21.6.3). If an exception occurs, its vector (in the range 0–31) is used to select a bit in the exception bitmap. If the bit is 1, a VM exit occurs; if the bit is 0, the exception is delivered normally through the guest IDT. This use of the exception bitmap applies also to exceptions generated by the instructions INT3, INTO, BOUND, and UD2.

Page faults (exceptions with vector 14) are specially treated. When a page fault occurs, a logical processor consults (1) bit 14 of the exception bitmap; (2) the error code produced with the page fault [PFEC]; (3) the page-fault error-code mask field [PFEC\_MASK]; and (4) the page-fault error-code match field [PFEC\_MATCH]. It checks if PFEC & PFEC\_MASK = PFEC\_MATCH. If there is equality, the specification of bit 14 in the exception bitmap is followed (for example, a VM exit occurs if that bit is set). If there is inequality, the meaning of that bit is reversed (for example, a VM exit occurs if that bit is clear).

Thus, if software desires VM exits on all page faults, it can set bit 14 in the exception bitmap to 1 and set the page-fault error-code mask and match fields each to 00000000H. If software desires VM exits on no page faults, it can set bit 14 in the exception bitmap to 1, the page-fault error-code mask field to 00000000H, and the page-fault error-code match field to FFFFFFFFH.

- **Triple fault.** A VM exit occurs if the logical processor encounters an exception while attempting to call the double-fault handler and that exception itself does not cause a VM exit due to the exception bitmap. This applies to the case in which the double-fault exception was generated within VMX non-root operation, the case in which the double-fault exception was generated during event injection by VM entry, and to the case in which VM entry is injecting a double-fault exception.
- **External interrupts.** An external interrupt causes a VM exit if the “external-interrupt exiting” VM-execution control is 1. Otherwise, the interrupt is delivered normally through the IDT. (If a logical processor is in the shutdown state or the wait-for-SIPI state, external interrupts are blocked. The interrupt is not delivered through the IDT and no VM exit occurs.)
- **Non-maskable interrupts (NMIs).** An NMI causes a VM exit if the “NMI exiting” VM-execution control is 1. Otherwise, it is delivered using descriptor 2 of

the IDT. (If a logical processor is in the wait-for-SIPI state, NMIs are blocked. The NMI is not delivered through the IDT and no VM exit occurs.)

- **INIT signals.** INIT signals cause VM exits. A logical processor performs none of the operations normally associated with these events. Such exits do not modify register state or clear pending events as they would outside of VMX operation. (If a logical processor is in the wait-for-SIPI state, INIT signals are blocked. They do not cause VM exits in this case.)
- **Start-up IPIs (SIPIs). SIPIs cause VM exits.** If a logical processor is not in the wait-for-SIPI activity state when a SIPI arrives, no VM exit occurs and the SIPI is discarded. VM exits due to SIPIs do not perform any of the normal operations associated with those events: they do not modify register state as they would outside of VMX operation. (If a logical processor is not in the wait-for-SIPI state, SIPIs are blocked. They do not cause VM exits in this case.)
- **Task switches.** Task switches are not allowed in VMX non-root operation. Any attempt to effect a task switch in VMX non-root operation causes a VM exit. See Section 22.6.2.
- **System-management interrupts (SMIs).** If the logical processor is using the dual-monitor treatment of SMIs and system-management mode (SMM), SMIs cause SMM VM exits. See Section 26.15.2.<sup>1</sup>
- **VMX-preemption timer.** A VM exit occurs when the timer counts down to zero. See Section 22.7.1 for details of operation of the VMX-preemption timer. As noted in that section, the timer does not cause VM exits if the logical processor is outside the C-states C0, C1, and C2.

Debug-trap exceptions and higher priority events take priority over VM exits caused by the VMX-preemption timer. VM exits caused by the VMX-preemption timer take priority over VM exits caused by the “NMI-window exiting” VM-execution control and lower priority events.

These VM exits wake a logical processor from the same inactive states as would a non-maskable interrupt. Specifically, they wake a logical processor from the shutdown state and from the states entered using the HLT and MWAIT instructions. These VM exits do not occur if the logical processor is in the wait-for-SIPI state.

In addition, there are controls that cause VM exits based on the readiness of guest software to receive interrupts:

- If the “interrupt-window exiting” VM-execution control is 1, a VM exit occurs before execution of any instruction if RFLAGS.IF = 1 and there is no blocking of events by STI or by MOV SS (see Table 21-3). Such a VM exit occurs immediately after VM entry if the above conditions are true (see Section 23.6.5).

---

1. Under the dual-monitor treatment of SMIs and SMM, SMIs also cause SMM VM exits if they occur in VMX root operation outside SMM. If the processor is using the default treatment of SMIs and SMM, SMIs are delivered as described in Section 26.14.1.

## VMX NON-ROOT OPERATION

Non-maskable interrupts (NMIs) and higher priority events take priority over VM exits caused by this control. VM exits caused by this control take priority over external interrupts and lower priority events.

These VM exits wake a logical processor from the same inactive states as would an external interrupt. Specifically, they wake a logical processor from the states entered using the HLT and MWAIT instructions. These VM exits do not occur if the logical processor is in the shutdown state or the wait-for-SIPI state.

- If the “NMI-window exiting” VM-execution control is 1, a VM exit occurs before execution of any instruction if there is no virtual-NMI blocking and there is no blocking of events by MOV SS (see Table 21-3). (A logical processor may also prevent such a VM exit if there is blocking of events by STI.) Such a VM exit occurs immediately after VM entry if the above conditions are true (see Section 23.6.6).

VM exits caused by the VMX-preemption timer and higher priority events take priority over VM exits caused by this control. VM exits caused by this control take priority over non-maskable interrupts (NMIs) and lower priority events.

These VM exits wake a logical processor from the same inactive states as would an NMI. Specifically, they wake a logical processor from the shutdown state and from the states entered using the HLT and MWAIT instructions. These VM exits do not occur if the logical processor is in the wait-for-SIPI state.

## 22.4 CHANGES TO INSTRUCTION BEHAVIOR IN VMX NON-ROOT OPERATION

The behavior of some instructions is changed in VMX non-root operation. Some of these changes are determined by the settings of certain VM-execution control fields. The following items detail such changes:

- **CLTS.** Behavior of the CLTS instruction is determined by the bits in position 3 (corresponding to CR0.TS) in the CR0 guest/host mask and the CR0 read shadow:
  - If bit 3 in the CR0 guest/host mask is 0, CLTS clears CR0.TS normally (the value of bit 3 in the CR0 read shadow is irrelevant in this case), unless CR0.TS is fixed to 1 in VMX operation (see Section 20.8), in which case CLTS causes a general-protection exception.
  - If bit 3 in the CR0 guest/host mask is 1 and bit 3 in the CR0 read shadow is 0, CLTS completes but does not change the contents of CR0.TS.
  - If the bits in position 3 in the CR0 guest/host mask and the CR0 read shadow are both 1, CLTS causes a VM exit (see Section 22.1.3).
- **IRET.** Behavior of IRET with regard to NMI blocking (see Table 21-3) is determined by the settings of the “NMI exiting” and “virtual NMIs” VM-execution controls:

- If the “NMI exiting” VM-execution control is 0, IRET operates normally and unblocks NMIs. (If the “NMI exiting” VM-execution control is 0, the “virtual NMIs” control must be 0; see Section 23.2.1.1.)
- If the “NMI exiting” VM-execution control is 1, IRET does not affect blocking of NMIs. If, in addition, the “virtual NMIs” VM-execution control is 1, the logical processor tracks virtual-NMI blocking. In this case, IRET removes any virtual-NMI blocking.

The unblocking of NMIs or virtual NMIs specified above occurs even if IRET causes a fault.

- **LMSW.** Outside of VMX non-root operation, LMSW loads its source operand into CRO[3:0], but it does not clear CRO.PE if that bit is set. In VMX non-root operation, an execution of LMSW that does not cause a VM exit (see Section 22.1.3) leaves unmodified any bit in CRO[3:0] corresponding to a bit set in the CRO guest/host mask. An attempt to set any other bit in CRO[3:0] to a value not supported in VMX operation (see Section 20.8) causes a general-protection exception. Attempts to clear CRO.PE are ignored without fault.
- **MOV from CRO.** The behavior of MOV from CRO is determined by the CRO guest/host mask and the CRO read shadow. For each position corresponding to a bit clear in the CRO guest/host mask, the destination operand is loaded with the value of the corresponding bit in CRO. For each position corresponding to a bit set in the CRO guest/host mask, the destination operand is loaded with the value of the corresponding bit in the CRO read shadow. Thus, if every bit is cleared in the CRO guest/host mask, MOV from CRO reads normally from CRO; if every bit is set in the CRO guest/host mask, MOV from CRO returns the value of the CRO read shadow.

Depending on the contents of the CRO guest/host mask and the CRO read shadow, bits may be set in the destination that would never be set when reading directly from CRO.

- **MOV from CR3.** If the “enable EPT” VM-execution control is 1 and an execution of MOV from CR3 does not cause a VM exit (see Section 22.1.3), the value loaded from CR3 is a guest-physical address; see Section 25.2.1.
- **MOV from CR4.** The behavior of MOV from CR4 is determined by the CR4 guest/host mask and the CR4 read shadow. For each position corresponding to a bit clear in the CR4 guest/host mask, the destination operand is loaded with the value of the corresponding bit in CR4. For each position corresponding to a bit set in the CR4 guest/host mask, the destination operand is loaded with the value of the corresponding bit in the CR4 read shadow. Thus, if every bit is cleared in the CR4 guest/host mask, MOV from CR4 reads normally from CR4; if every bit is set in the CR4 guest/host mask, MOV from CR4 returns the value of the CR4 read shadow.

Depending on the contents of the CR4 guest/host mask and the CR4 read shadow, bits may be set in the destination that would never be set when reading directly from CR4.

## VMX NON-ROOT OPERATION

- **MOV from CR8.** Behavior of the MOV from CR8 instruction (which can be executed only in 64-bit mode) is determined by the settings of the “CR8-store exiting” and “use TPR shadow” VM-execution controls:
  - If both controls are 0, MOV from CR8 operates normally.
  - If the “CR8-store exiting” VM-execution control is 0 and the “use TPR shadow” VM-execution control is 1, MOV from CR8 reads from the TPR shadow. Specifically, it loads bits 3:0 of its destination operand with the value of bits 7:4 of byte 80H of the virtual-APIC page (see Section 21.6.8). Bits 63:4 of the destination operand are cleared.
  - If the “CR8-store exiting” VM-execution control is 1, MOV from CR8 causes a VM exit (see Section 22.1.3); the “use TPR shadow” VM-execution control is ignored in this case.
- **MOV to CRO.** An execution of MOV to CRO that does not cause a VM exit (see Section 22.1.3) leaves unmodified any bit in CRO corresponding to a bit set in the CRO guest/host mask. Treatment of attempts to modify other bits in CRO depends on the setting of the “unrestricted guest” VM-execution control:<sup>1</sup>
  - If the control is 0, MOV to CRO causes a general-protection exception if it attempts to set any bit in CRO to a value not supported in VMX operation (see Section 20.8).
  - If the control is 1, MOV to CRO causes a general-protection exception if it attempts to set any bit in CRO other than bit 0 (PE) or bit 31 (PG) to a value not supported in VMX operation. It remains the case, however, that MOV to CRO causes a general-protection exception if it would result in CRO.PE = 0 and CRO.PG = 1 or if it would result in CRO.PG = 1, CR4.PAE = 0, and IA32\_EFER.LME = 1.
- **MOV to CR3.** If the “enable EPT” VM-execution control is 1 and an execution of MOV to CR3 does not cause a VM exit (see Section 22.1.3), the value loaded into CR3 is treated as a guest-physical address; see Section 25.2.1.
  - If PAE paging is not being used, the instruction does not use the guest-physical address to access memory and it does not cause it to be translated through EPT.<sup>2</sup>
  - If PAE paging is being used, the instruction translates the guest-physical address through EPT and uses the result to load the four (4) page-directory-pointer-table entries (PDPTEs). The instruction does not use the guest-physical addresses the PDPTEs to access memory and it does not cause them to be translated through EPT.

- 
1. “Unrestricted guest” is a secondary processor-based VM-execution control. If bit 31 of the primary processor-based VM-execution controls is 0, VMX non-root operation functions as if the “unrestricted guest” VM-execution control were 0. See Section 21.6.2.
  2. A logical processor uses PAE paging if CRO.PG = 1, CR4.PAE = 1 and IA32\_EFER.LMA = 0. See Section 4.4 in the *Intel® 64 and IA-32 Architectures Software Developer’s Manual, Volume 3A*.

- **MOV to CR4.** An execution of MOV to CR4 that does not cause a VM exit (see Section 22.1.3) leaves unmodified any bit in CR4 corresponding to a bit set in the CR4 guest/host mask. Such an execution causes a general-protection exception if it attempts to set any bit in CR4 (not corresponding to a bit set in the CR4 guest/host mask) to a value not supported in VMX operation (see Section 20.8).
- **MOV to CR8.** Behavior of the MOV to CR8 instruction (which can be executed only in 64-bit mode) is determined by the settings of the “CR8-load exiting” and “use TPR shadow” VM-execution controls:
  - If both controls are 0, MOV to CR8 operates normally.
  - If the “CR8-load exiting” VM-execution control is 0 and the “use TPR shadow” VM-execution control is 1, MOV to CR8 writes to the TPR shadow. Specifically, it stores bits 3:0 of its source operand into bits 7:4 of byte 80H of the virtual-APIC page (see Section 21.6.8); bits 3:0 of that byte and bytes 129-131 of that page are cleared. Such a store may cause a VM exit to occur after it completes (see Section 22.1.3).
  - If the “CR8-load exiting” VM-execution control is 1, MOV to CR8 causes a VM exit (see Section 22.1.3); the “use TPR shadow” VM-execution control is ignored in this case.
- **MWAIT.** Behavior of the MWAIT instruction (which always causes an invalid-opcode exception—#UD—if CPL > 0) is determined by the setting of the “MWAIT exiting” VM-execution control:
  - If the “MWAIT exiting” VM-execution control is 1, MWAIT causes a VM exit (see Section 22.1.3).
  - If the “MWAIT exiting” VM-execution control is 0, MWAIT operates normally if any of the following is true: (1) the “interrupt-window exiting” VM-execution control is 0; (2) ECX[0] is 0; or (3) RFLAGS.IF = 1.
  - If the “MWAIT exiting” VM-execution control is 0, the “interrupt-window exiting” VM-execution control is 1, ECX[0] = 1, and RFLAGS.IF = 0, MWAIT does not cause the processor to enter an implementation-dependent optimized state; instead, control passes to the instruction following the MWAIT instruction.
- **RDMSR.** Section 22.1.3 identifies when executions of the RDMSR instruction cause VM exits. If such an execution causes neither a fault due to CPL > 0 nor a VM exit, the instruction’s behavior may be modified for certain values of ECX:
  - If ECX contains 10H (indicating the IA32\_TIME\_STAMP\_COUNTER MSR), the value returned by the instruction is determined by the setting of the “use TSC offsetting” VM-execution control as well as the TSC offset:
    - If the control is 0, the instruction operates normally, loading EAX:EDX with the value of the IA32\_TIME\_STAMP\_COUNTER MSR.
    - If the control is 1, the instruction loads EAX:EDX with the sum (using signed addition) of the value of the IA32\_TIME\_STAMP\_COUNTER MSR and the value of the TSC offset (interpreted as a signed value).

## VMX NON-ROOT OPERATION

The 1-setting of the “use TSC-offsetting” VM-execution control does not effect executions of RDMSR if ECX contains 6E0H (indicating the IA32\_TSC\_DEADLINE MSR). Such executions return the APIC-timer deadline relative to the actual timestamp counter without regard to the TSC offset.

- If ECX contains 808H (indicating the TPR MSR), instruction behavior is determined by the setting of the “virtualize x2APIC mode” VM-execution control:<sup>1</sup>
  - If the control is 0, the instruction operates normally. If the local APIC is in x2APIC mode, EAX[7:0] is loaded with the value of the APIC’s task-priority register (EDX and EAX[31:8] are cleared to 0). If the local APIC is not in x2APIC mode, a general-protection fault occurs.
  - If the control is 1, the instruction loads EAX:EDX with the value of bytes 87H:80H of the virtual-APIC page. This occurs even if the local APIC is not in x2APIC mode (no general-protection fault occurs because the local APIC is not x2APIC mode).
- **RDTSC.** Behavior of the RDTSC instruction is determined by the settings of the “RDTSC exiting” and “use TSC offsetting” VM-execution controls as well as the TSC offset:
  - If both controls are 0, RDTSC operates normally.
  - If the “RDTSC exiting” VM-execution control is 0 and the “use TSC offsetting” VM-execution control is 1, RDTSC loads EAX:EDX with the sum (using signed addition) of the value of the IA32\_TIME\_STAMP\_COUNTER MSR and the value of the TSC offset (interpreted as a signed value).
  - If the “RDTSC exiting” VM-execution control is 1, RDTSC causes a VM exit (see Section 22.1.3).
- **RDTSCP.** Behavior of the RDTSCP instruction is determined first by the setting of the “enable RDTSCP” VM-execution control:<sup>2</sup>
  - If the “enable RDTSCP” VM-execution control is 0, RDTSCP causes an invalid-opcode exception (#UD).
  - If the “enable RDTSCP” VM-execution control is 1, treatment is based on the settings the “RDTSC exiting” and “use TSC offsetting” VM-execution controls as well as the TSC offset:
    - If both controls are 0, RDTSCP operates normally.

- 
1. “Virtualize x2APIC mode” is a secondary processor-based VM-execution control. If bit 31 of the primary processor-based VM-execution controls is 0, VMX non-root operation functions as if the “virtualize x2APIC mode” VM-execution control were 0. See Section 21.6.2.
  2. “Enable RDTSCP” is a secondary processor-based VM-execution control. If bit 31 of the primary processor-based VM-execution controls is 0, VMX non-root operation functions as if the “enable RDTSCP” VM-execution control were 0. See Section 21.6.2.

- If the “RDTSC exiting” VM-execution control is 0 and the “use TSC offsetting” VM-execution control is 1, RDTSCP loads EAX:EDX with the sum (using signed addition) of the value of the IA32\_TIME\_STAMP\_COUNTER MSR and the value of the TSC offset (interpreted as a signed value); it also loads ECX with the value of bits 31:0 of the IA32\_TSC\_AUX MSR.
- If the “RDTSC exiting” VM-execution control is 1, RDTSCP causes a VM exit (see Section 22.1.3).
- **SMSW.** The behavior of SMSW is determined by the CRO guest/host mask and the CRO read shadow. For each position corresponding to a bit clear in the CRO guest/host mask, the destination operand is loaded with the value of the corresponding bit in CRO. For each position corresponding to a bit set in the CRO guest/host mask, the destination operand is loaded with the value of the corresponding bit in the CRO read shadow. Thus, if every bit is cleared in the CRO guest/host mask, MOV from CRO reads normally from CRO; if every bit is set in the CRO guest/host mask, MOV from CRO returns the value of the CRO read shadow.

Note the following: (1) for any memory destination or for a 16-bit register destination, only the low 16 bits of the CRO guest/host mask and the CRO read shadow are used (bits 63:16 of a register destination are left unchanged); (2) for a 32-bit register destination, only the low 32 bits of the CRO guest/host mask and the CRO read shadow are used (bits 63:32 of the destination are cleared); and (3) depending on the contents of the CRO guest/host mask and the CRO read shadow, bits may be set in the destination that would never be set when reading directly from CRO.

- **WRMSR.** Section 22.1.3 identifies when executions of the WRMSR instruction cause VM exits. If such an execution neither a fault due to CPL > 0 nor a VM exit, the instruction’s behavior may be modified for certain values of ECX:
  - If ECX contains 79H (indicating IA32 BIOS\_UPDT\_TRIG MSR), no microcode update is loaded, and control passes to the next instruction. This implies that microcode updates cannot be loaded in VMX non-root operation.
  - If ECX contains 808H (indicating the TPR MSR) and either EDX or EAX[31:8] is non-zero, a general-protection fault occurs (this is true even if the logical processor is not in VMX non-root operation). Otherwise, instruction behavior is determined by the setting of the “virtualize x2APIC mode” VM-execution control and the value of the TPR-threshold VM-execution control field:
    - If the control is 0, the instruction operates normally. If the local APIC is in x2APIC mode, the value of EAX[7:0] is written to the APIC’s task-priority register. If the local APIC is not in x2APIC mode, a general-protection fault occurs.
    - If the control is 1, the instruction stores the value of EAX:EDX to bytes 87H:80H of the virtual-APIC page. This store occurs even if the local APIC is not in x2APIC mode (no general-protection fault occurs)

because the local APIC is not x2APIC mode). The store may cause a VM exit to occur after the instruction completes (see Section 22.1.3).

- The 1-setting of the “use TSC-offsetting” VM-execution control does not effect executions of WRMSR if ECX contains 10H (indicating the IA32\_TIME\_STAMP\_COUNTER MSR). Such executions modify the actual timestamp counter without regard to the TSC offset.
- The 1-setting of the “use TSC-offsetting” VM-execution control does not effect executions of WRMSR if ECX contains 6EOH (indicating the IA32\_TSC\_DEADLINE MSR). Such executions modify the APIC-timer deadline relative to the actual timestamp counter without regard to the TSC offset.

## 22.5 APIC ACCESSES THAT DO NOT CAUSE VM EXITS

As noted in Section 22.2, if the “virtualize APIC accesses” VM-execution control is 1, most memory accesses to the APIC-access page (see Section 21.6.2) cause APIC-access VM exits.<sup>1</sup> Section 22.2 identifies potential exceptions. These are covered in Section 22.5.1 through Section 22.5.3.

In some cases, an attempt to access memory on the APIC-access page is converted to an access to the virtual-APIC page (see Section 21.6.8). In these cases, the access uses the memory type reported in bit 53:50 of the IA32\_VMX\_BASIC MSR (see Appendix G.1).

### 22.5.1 Linear Accesses to the APIC-Access Page Using Large-Page Translations

As noted in Section 22.2.1, a linear access to the APIC-access page using translation with a large page (2-MByte, 4-MByte, or 1-GByte) may or may not cause an APIC-access VM exit. If it does not and the access is not a VTPR access (see Section 22.2.4), the access operates on memory on the APIC-access page. Section 22.5.3 describes the treatment if there is no APIC-access VM exit and the access is a VTPR access.

### 22.5.2 Physical Accesses to the APIC-Access Page

A physical access to the APIC-access page may or may not cause an APIC-access VM exit. If it does not and the access is not a VTPR access (see Section 22.2.4), the access operates on memory on the APIC-access page (this may happen if the access

---

1. “Virtualize APIC accesses” is a secondary processor-based VM-execution control. If bit 31 of the primary processor-based VM-execution controls is 0, VMX non-root operation functions as if the “virtualize APIC accesses” VM-execution control were 0. See Section 21.6.2.

causes an APIC-access VM exit). Section 22.5.3 describes the treatment if there is no APIC-access VM exit and the access is a VTPR access.

### 22.5.3 VTPR Accesses

As noted in Section 22.2.4, a memory access is a VTPR access if all of the following hold: (1) the “use TPR shadow” VM-execution control is 1; (2) the access is not for an instruction fetch; (3) the access is at most 32 bits in width; and (4) the access is to offset 80H on the APIC-access page.

The treatment of VTPR accesses depends on the nature of the access:

- A linear VTPR access using a translation with a 4-KByte page does not cause an APIC-access VM exit. Instead, it is converted so that, instead of accessing offset 80H on the APIC-access page, it accesses offset 80H on the virtual-APIC page. Further details are provided in Section 22.5.3.1 to Section 22.5.3.3.
- A linear VTPR access using a translation with a large page (2-MByte, 4-MByte, or 1-GByte) may be treated in either of two ways:
  - It may operate on memory on the APIC-access page. The details in Section 22.5.3.1 to Section 22.5.3.3 do not apply.
  - It may be converted so that, instead of accessing offset 80H on the APIC-access page, it accesses offset 80H on the virtual-APIC page. Further details are provided in Section 22.5.3.1 to Section 22.5.3.3.
- A physical VTPR access may be treated in one of three ways:
  - It may cause an APIC-access VM exit. The details in Section 22.5.3.1 to Section 22.5.3.3 do not apply.
  - It may operate on memory on the APIC-access page (and possibly then cause an APIC-access VM exit). The details in Section 22.5.3.1 to Section 22.5.3.3 do not apply.
  - It may be converted so that, instead of accessing offset 80H on the APIC-access page, it accesses offset 80H on the virtual-APIC page. Further details are provided in Section 22.5.3.1 to Section 22.5.3.3.

Linear VTPR accesses never cause APIC-access VM exits (recall that an access is a VTPR access only if the “use TPR shadow” VM-execution control is 1).

#### 22.5.3.1 Treatment of Individual VTPR Accesses

The following items detail the treatment of VTPR accesses:

- VTPR read accesses. Such an access completes normally (reading data from the field at offset 80H on the virtual-APIC page).

The following items detail certain instructions that are considered to perform read accesses and how they behavior when accessing the VTPR:

## VMX NON-ROOT OPERATION

- A VTPR access using the CLFLUSH instruction flushes data for offset 80H on the virtual-APIC page.
- A VTPR access using the LMSW instruction may cause a VM exit due to the CRO guest/host mask and the CRO read shadow.
- A VTPR access using the MONITOR instruction causes the logical processor to monitor offset 80H on the virtual-APIC page.
- A VTPR access using the PREFETCH instruction may prefetch data; if so, it is from offset 80H on the virtual-APIC page.
- VTPR write accesses. Such an access completes normally (writing data to the field at offset 80H on the virtual-APIC page) and causes a TPR-shadow update (see Section 22.5.3.3).

The following items detail certain instructions that are considered to perform write accesses and how they behavior when accessing the VTPR:

- The ENTER instruction is considered to write to VTPR if the byte referenced by the final value of the stack pointer is at offset 80H on the APIC-access page (even though ENTER does not write to that byte if its size operand is non-zero). The instruction is followed by a TPR-shadow update.
- A VTPR access using the SMSW instruction stores data determined by the current CRO contents, the CRO guest/host mask, and the CRO read shadow. The instruction is followed by a TPR-shadow update.

### 22.5.3.2 Operations with Multiple Accesses

Some operations may access multiple addresses. These operations include the execution of some instructions and the delivery of events through the IDT (including those injected with VM entry). In some cases, the Intel® 64 architecture specifies the ordering of these memory accesses. The following items describe the treatment of VTPR accesses that are part of such multi-access operations:

- Read-modify-write instructions may first perform a VTPR read access and then a VTPR write access. Both accesses complete normally (as described in Section 22.5.3.1). The instruction is followed by a TPR-shadow update (see Section 22.5.3.3).
- Some operations may perform a VTPR write access and subsequently cause a fault. This situation is treated as follows:
  - If the fault leads to a VM exit, no TPR-shadow update occurs.
  - If the fault does not lead to a VM exit, a TPR-shadow update occurs after fault delivery completes and before execution of the fault handler.
- If an operation includes a VTPR access and an access to some other field on the APIC-access page, the latter access causes an APIC-access VM exit as described in Section 22.2.

If the operation performs a VTPR write access before the APIC-access VM exit, there is no TPR-shadow update.

- Suppose that the first iteration of a repeated string instruction (including OUTS) that accesses the APIC-access page performs a VTPR read access and that the next iteration would read from the APIC-access page using an offset other than 80H. The following items describe the behavior of the logical processor:
  - The iteration that performs the VTPR read access completes successfully, reading data from offset 80H on the virtual-APIC page.
  - The iteration that would read from the other offset causes an APIC-access VM exit. The instruction pointer saved in the VMCS references the repeated string instruction and the values of the general-purpose registers are such that iteration would be repeated if the instruction were restarted.
- Suppose that the first iteration of a repeated string instruction (including INS) that accesses the APIC-access page performs a VTPR write access and that the next iteration would write to the APIC-access page using an offset other than 80H. The following items describe the behavior of the logical processor:
  - The iteration that performs the VTPR write access writes data to offset 80H on the virtual-APIC page. The write is followed by a TPR-shadow update, which may cause a VM exit (see Section 22.5.3.3).
  - If the TPR-shadow update does cause a VM exit, the instruction pointer saved in the VMCS references the repeated string instruction and the values of the general-purpose registers are such that the next iteration would be performed if the instruction were restarted.
  - If the TPR-shadow update does not cause a VM exit, the iteration that would write to the other offset causes an APIC-access VM exit. The instruction pointer saved in the VMCS references the repeated string instruction and the values of the general-purpose registers are such that that iteration would be repeated if the instruction were restarted.
- Suppose that the last iteration of a repeated string instruction (including INS) performs a VTPR write access. The iteration writes data to offset 80H on the virtual-APIC page. The write is followed by a TPR-shadow update, which may cause a VM exit (see Section 22.5.3.3). If it does, the instruction pointer saved in the VMCS references the instruction after the string instruction and the values of the general-purpose registers reflect completion of the string instruction.

### 22.5.3.3 TPR-Shadow Updates

If the “use TPR shadow” and “virtualize APIC accesses” VM-execution controls are both 1, a logical processor performs certain actions after any operation (or iteration of a repeated string instruction) with a VTPR write access. These actions are called a **TPR-shadow update**. (As noted in Section 22.5.3.2, a TPR-shadow update does not occur following an access that causes a VM exit.)

A TPR-shadow update includes the following actions:

1. Bits 31:8 at offset 80H on the virtual-APIC page are cleared.

## VMX NON-ROOT OPERATION

2. If the value of bits 3:0 of the TPR threshold VM-execution control field is greater than the value of bits 7:4 at offset 80H on the virtual-APIC page, a VM exit will occur.

TPR-shadow updates take priority over system-management interrupts (SMIs), INIT signals, and lower priority events. A TPR-shadow update thus has priority over any debug exceptions that may have been triggered by the operation causing the TPR-shadow update. TPR-shadow updates (and any VM exits they cause) are not blocked if RFLAGS.IF = 0 or by the MOV SS, POP SS, or STI instructions.

## 22.6 OTHER CHANGES IN VMX NON-ROOT OPERATION

Treatments of event blocking and of task switches differ in VMX non-root operation as described in the following sections.

### 22.6.1 Event Blocking

Event blocking is modified in VMX non-root operation as follows:

- If the “external-interrupt exiting” VM-execution control is 1, RFLAGS.IF does not control the blocking of external interrupts. In this case, an external interrupt that is not blocked for other reasons causes a VM exit (even if RFLAGS.IF = 0).
- If the “external-interrupt exiting” VM-execution control is 1, external interrupts may or may not be blocked by STI or by MOV SS (behavior is implementation-specific).
- If the “NMI exiting” VM-execution control is 1, non-maskable interrupts (NMIs) may or may not be blocked by STI or by MOV SS (behavior is implementation-specific).

### 22.6.2 Treatment of Task Switches

Task switches are not allowed in VMX non-root operation. Any attempt to effect a task switch in VMX non-root operation causes a VM exit. However, the following checks are performed (in the order indicated), possibly resulting in a fault, before there is any possibility of a VM exit due to task switch:

1. If a task gate is being used, appropriate checks are made on its P bit and on the proper values of the relevant privilege fields. The following cases detail the privilege checks performed:
  - a. If CALL, INT *n*, or JMP accesses a task gate in IA-32e mode, a general-protection exception occurs.
  - b. If CALL, INT *n*, INT3, INTO, or JMP accesses a task gate outside IA-32e mode, privilege-levels checks are performed on the task gate but, if they pass,

- privilege levels are not checked on the referenced task-state segment (TSS) descriptor.
- c. If CALL or JMP accesses a TSS descriptor directly in IA-32e mode, a general-protection exception occurs.
  - d. If CALL or JMP accesses a TSS descriptor directly outside IA-32e mode, privilege levels are checked on the TSS descriptor.
  - e. If a non-maskable interrupt (NMI), an exception, or an external interrupt accesses a task gate in the IDT in IA-32e mode, a general-protection exception occurs.
  - f. If a non-maskable interrupt (NMI), an exception other than breakpoint exceptions (#BP) and overflow exceptions (#OF), or an external interrupt accesses a task gate in the IDT outside IA-32e mode, no privilege checks are performed.
  - g. If IRET is executed with RFLAGS.NT = 1 in IA-32e mode, a general-protection exception occurs.
  - h. If IRET is executed with RFLAGS.NT = 1 outside IA-32e mode, a TSS descriptor is accessed directly and no privilege checks are made.
2. Checks are made on the new TSS selector (for example, that is within GDT limits).
  3. The new TSS descriptor is read. (A page fault results if a relevant GDT page is not present).
  4. The TSS descriptor is checked for proper values of type (depends on type of task switch), P bit, S bit, and limit.

Only if checks 1–4 all pass (do not generate faults) might a VM exit occur. However, the ordering between a VM exit due to a task switch and a page fault resulting from accessing the old TSS or the new TSS is implementation-specific. Some logical processors may generate a page fault (instead of a VM exit due to a task switch) if accessing either TSS would cause a page fault. Other logical processors may generate a VM exit due to a task switch even if accessing either TSS would cause a page fault.

If an attempt at a task switch through a task gate in the IDT causes an exception (before generating a VM exit due to the task switch) and that exception causes a VM exit, information about the event whose delivery that accessed the task gate is recorded in the IDT-vectoring information fields and information about the exception that caused the VM exit is recorded in the VM-exit interruption-information fields. See Section 24.2. The fact that a task gate was being accessed is not recorded in the VMCS.

If an attempt at a task switch through a task gate in the IDT causes VM exit due to the task switch, information about the event whose delivery accessed the task gate is recorded in the IDT-vectoring fields of the VMCS. Since the cause of such a VM exit is a task switch and not an interruption, the valid bit for the VM-exit interruption information field is 0. See Section 24.2.

## 22.7 FEATURES SPECIFIC TO VMX NON-ROOT OPERATION

Some VM-execution controls cause VM exits using features that are specific to VMX non-root operation. These are the VMX-preemption timer (Section 22.7.1) and the monitor trap flag (Section 22.7.2).

### 22.7.1 VMX-Preemption Timer

If the last VM entry was performed with the 1-setting of “activate VMX-preemption timer” VM-execution control, the **VMX-preemption timer** counts down (from the value loaded by VM entry; see Section 23.6.4) in VMX non-root operation. When the timer counts down to zero, it stops counting down and a VM exit occurs (see Section 22.3).

The VMX-preemption timer counts down at rate proportional to that of the timestamp counter (TSC). Specifically, the timer counts down by 1 every time bit X in the TSC changes due to a TSC increment. The value of X is in the range 0–31 and can be determined by consulting the VMX capability MSR IA32\_VMX\_MISC (see Appendix G.6).

The VMX-preemption timer operates in the C-states C0, C1, and C2; it also operates in the shutdown and wait-for-SIPI states. If the timer counts down to zero in C1, C2, or shutdown, the logical processor transitions to the C0 C-state and causes a VM exit. (The timer does not cause a VM exit if it counts down to zero in the wait-for-SIPI state.) The timer is not decremented and does not cause VM exits in C-states deeper than C2.

Treatment of the timer in the case of system management interrupts (SMIs) and system-management mode (SMM) depends on whether the treatment of SMIs and SMM:

- If the default treatment of SMIs and SMM (see Section 26.14) is active, the VMX-preemption timer counts across an SMI to VMX non-root operation, subsequent execution in SMM, and the return from SMM via the RSM instruction. However, the timer can cause a VM exit only from VMX non-root operation. If the timer expires during SMI, in SMM, or during RSM, a timer-induced VM exit occurs immediately after RSM with its normal priority unless it is blocked based on activity state (Section 22.3).
- If the dual-monitor treatment of SMIs and SMM (see Section 26.15) is active, transitions into and out of SMM are VM exits and VM entries, respectively. The treatment of the VMX-preemption timer by those transitions is mostly the same as for ordinary VM exits and VM entries; Section 26.15.2 and Section 26.15.4 detail some differences.

## 22.7.2 Monitor Trap Flag

The **monitor trap flag** is a debugging feature that causes VM exits to occur on certain instruction boundaries in VMX non-root operation. Such VM exits are called **MTF VM exits**. An MTF VM exit may occur on an instruction boundary in VMX non-root operation as follows:

- If the “monitor trap flag” VM-execution control is 1 and VM entry is injecting a vectored event (see Section 23.5.1), an MTF VM exit is pending on the instruction boundary before the first instruction following the VM entry.
- If VM entry is injecting a pending MTF VM exit (see Section 23.5.2), an MTF VM exit is pending on the instruction boundary before the first instruction following the VM entry. This is the case even if the “monitor trap flag” VM-execution control is 0.
- If the “monitor trap flag” VM-execution control is 1, VM entry is not injecting an event, and a pending event (e.g., debug exception or interrupt) is delivered before an instruction can execute, an MTF VM exit is pending on the instruction boundary following delivery of the event (or any nested exception).
- Suppose that the “monitor trap flag” VM-execution control is 1, VM entry is not injecting an event, and the first instruction following VM entry is a REP-prefixed string instruction:
  - If the first iteration of the instruction causes a fault, an MTF VM exit is pending on the instruction boundary following delivery of the fault (or any nested exception).
  - If the first iteration of the instruction does not cause a fault, an MTF VM exit is pending on the instruction boundary after that iteration.
- Suppose that the “monitor trap flag” VM-execution control is 1, VM entry is not injecting an event, and the first instruction following VM entry is **not** a REP-prefixed string instruction:
  - If the instruction causes a fault, an MTF VM exit is pending on the instruction boundary following delivery of the fault (or any nested exception).<sup>1</sup>
  - If the instruction does not cause a fault, an MTF VM exit is pending on the instruction boundary following execution of that instruction. If the instruction is INT3 or INTO, this boundary follows delivery of any software exception. If the instruction is INT *n*, this boundary follows delivery of a software interrupt. If the instruction is HLT, the MTF VM exit will be from the HLT activity state.

No MTF VM exit occurs if another VM exit occurs before reaching the instruction boundary on which an MTF VM exit would be pending (e.g., due to an exception or triple fault).

---

1. This item includes the cases of an invalid opcode exception—#UD—generated by the UD2 instruction and a BOUND-range exceeded exception—#BR—generated by the BOUND instruction.

## VMX NON-ROOT OPERATION

An MTF VM exit occurs on the instruction boundary on which it is pending unless a higher priority event takes precedence or the MTF VM exit is blocked due to the activity state:

- System-management interrupts (SMIs), INIT signals, and higher priority events take priority over MTF VM exits. MTF VM exits take priority over debug-trap exceptions and lower priority events.
- No MTF VM exit occurs if the processor is in either the shutdown activity state or wait-for-SIPI activity state. If a non-maskable interrupt subsequently takes the logical processor out of the shutdown activity state without causing a VM exit, an MTF VM exit is pending after delivery of that interrupt.

### 22.7.3 Translation of Guest-Physical Addresses Using EPT

The extended page-table mechanism (EPT) is a feature that can be used to support the virtualization of physical memory. When EPT is in use, certain physical addresses are treated as guest-physical addresses and are not used to access memory directly. Instead, guest-physical addresses are translated by traversing a set of EPT paging structures to produce physical addresses that are used to access memory.

Details of the EPT are given in Section 25.2.

## 22.8 UNRESTRICTED GUESTS

The first processors to support VMX operation require CR0.PE and CR0.PG to be 1 in VMX operation (see Section 20.8). This restriction implies that guest software cannot be run in unpaged protected mode or in real-address mode. Later processors support a VM-execution control called “unrestricted guest”.<sup>1</sup> If this control is 1, CR0.PE and CR0.PG may be 0 in VMX non-root operation. Such processors allow guest software to run in unpaged protected mode or in real-address mode. The following items describe the behavior of such software:

- The MOV CR0 instructions does not cause a general-protection exception simply because it would set either CR0.PE and CR0.PG to 0. See Section 22.4 for details.
- A logical processor treats the values of CR0.PE and CR0.PG in VMX non-root operation just as it does outside VMX operation. Thus, if CR0.PE = 0, the processor operates as it does normally in real-address mode (for example, it uses the 16-bit **interrupt table** to deliver interrupts and exceptions). If CR0.PG = 0, the processor operates as it does normally when paging is disabled.
- Processor operation is modified by the fact that the processor is in VMX non-root operation and by the settings of the VM-execution controls just as it is in

---

1. “Unrestricted guest” is a secondary processor-based VM-execution control. If bit 31 of the primary processor-based VM-execution controls is 0, VMX non-root operation functions as if the “unrestricted guest” VM-execution control were 0. See Section 21.6.2.

protected mode or when paging is enabled. Instructions, interrupts, and exceptions that cause VM exits in protected mode or when paging is enabled also do so in real-address mode or when paging is disabled. The following examples should be noted:

- If CR0.PG = 0, page faults do not occur and thus cannot cause VM exits.
- If CR0.PE = 0, invalid-TSS exceptions do not occur and thus cannot cause VM exits.
- If CR0.PE = 0, the following instructions cause invalid-opcode exceptions and do not cause VM exits: INVEPT, INVVPID, LLDT, LTR, SLDT, STR, VMCLEAR, VMLAUNCH, VMPTRLD, VMPTRST, VMREAD, VMRESUME, VMWRITE, VMXOFF, and VMXON.
- If CR0.PG = 0, each linear address is passed directly to the EPT mechanism for translation to a physical address.<sup>1</sup> The guest memory type passed on to the EPT mechanism is WB (writeback).

---

1. As noted in Section 23.2.1.1, the “enable EPT” VM-execution control must be 1 if the “unrestricted guest” VM-execution control is 1.

## VMX NON-ROOT OPERATION

## CHAPTER 23

### VM ENTRIES

---

Software can enter VMX non-root operation using either of the VM-entry instructions VMLAUNCH and VMRESUME. VMLAUNCH can be used only with a VMCS whose launch state is clear and VMRESUME can be used only with a VMCS whose the launch state is launched. VMLAUNCH should be used for the first VM entry after VMCLEAR; VMRESUME should be used for subsequent VM entries with the same VMCS.

Each VM entry performs the following steps in the order indicated:

1. Basic checks are performed to ensure that VM entry can commence (Section 23.1).
2. The control and host-state areas of the VMCS are checked to ensure that they are proper for supporting VMX non-root operation and that the VMCS is correctly configured to support the next VM exit (Section 23.2).
3. The following may be performed in parallel or in any order (Section 23.3):
  - The guest-state area of the VMCS is checked to ensure that, after the VM entry completes, the state of the logical processor is consistent with IA-32 and Intel 64 architectures.
  - Processor state is loaded from the guest-state area and based on controls in the VMCS.
  - Address-range monitoring is cleared.
4. MSRs are loaded from the VM-entry MSR-load area (Section 23.4).
5. If VMLAUNCH is being executed, the launch state of the VMCS is set to “launched.”
6. An event may be injected in the guest context (Section 23.5).

Steps 1–4 above perform checks that may cause VM entry to fail. Such failures occur in one of the following three ways:

- Some of the checks in Section 23.1 may generate ordinary faults (for example, an invalid-opcode exception). Such faults are delivered normally.
- Some of the checks in Section 23.1 and all the checks in Section 23.2 cause control to pass to the instruction following the VM-entry instruction. The failure is indicated by setting RFLAGS.ZF<sup>1</sup> (if there is a current VMCS) or RFLAGS.CF (if there is no current VMCS). If there is a current VMCS, an error number indicating the cause of the failure is stored in the VM-instruction error field. See Chapter 5

---

1. This chapter uses the notation RAX, RIP, RSP, RFLAGS, etc. for processor registers because most processors that support VMX operation also support Intel 64 architecture. For IA-32 processors, this notation refers to the 32-bit forms of those registers (EAX, EIP, ESP, EFLAGS, etc.). In a few places, notation such as EAX is used to refer specifically to lower 32 bits of the indicated register.

## VM ENTRIES

of the *Intel® 64 and IA-32 Architectures Software Developer’s Manual, Volume 2B* for the error numbers.

- The checks in Section 23.3 and Section 23.4 cause processor state to be loaded from the host-state area of the VMCS (as would be done on a VM exit). Information about the failure is stored in the VM-exit information fields. See Section 23.7 for details.

EFLAGS.TF = 1 causes a VM-entry instruction to generate a single-step debug exception only if failure of one of the checks in Section 23.1 and Section 23.2 causes control to pass to the following instruction. A VM-entry does not generate a single-step debug exception in any of the following cases: (1) the instruction generates a fault; (2) failure of one of the checks in Section 23.3 or in loading MSRs causes processor state to be loaded from the host-state area of the VMCS; or (3) the instruction passes all checks in Section 23.1, Section 23.2, and Section 23.3 and there is no failure in loading MSRs.

Section 26.15 describes the dual-monitor treatment of system-management interrupts (SMIs) and system-management mode (SMM). Under this treatment, code running in SMM returns using VM entries instead of the RSM instruction. A VM entry **returns from SMM** if it is executed in SMM and the “entry to SMM” VM-entry control is 0. VM entries that return from SMM differ from ordinary VM entries in ways that are detailed in Section 26.15.4.

### 23.1 BASIC VM-ENTRY CHECKS

Before a VM entry commences, the current state of the logical processor is checked in the following order:

1. If the logical processor is in virtual-8086 mode or compatibility mode, an invalid-opcode exception is generated.
2. If the current privilege level (CPL) is not zero, a general-protection exception is generated.
3. If there is no current VMCS, RFLAGS.CF is set to 1 and control passes to the next instruction.
4. If there is a current VMCS, the following conditions are evaluated in order; any of these cause VM entry to fail:
  - a. if there is MOV-SS blocking (see Table 21-3)
  - b. if the VM entry is invoked by VMLAUNCH and the VMCS launch state is not clear
  - c. if the VM entry is invoked by VMRESUME and the VMCS launch state is not launched

If any of these checks fail, RFLAGS.ZF is set to 1 and control passes to the next instruction. An error number indicating the cause of the failure is stored in the

VM-instruction error field. See Chapter 5 of the *Intel® 64 and IA-32 Architectures Software Developer’s Manual, Volume 2B* for the error numbers.

## 23.2 CHECKS ON VMX CONTROLS AND HOST-STATE AREA

If the checks in Section 23.1 do not cause VM entry to fail, the control and host-state areas of the VMCS are checked to ensure that they are proper for supporting VMX non-root operation, that the VMCS is correctly configured to support the next VM exit, and that, after the next VM exit, the processor’s state is consistent with the Intel 64 and IA-32 architectures.

VM entry fails if any of these checks fail. When such failures occur, control is passed to the next instruction, RFLAGS.ZF is set to 1 to indicate the failure, and the VM-instruction error field is loaded with an error number that indicates whether the failure was due to the controls or the host-state area (see Chapter 5 of the *Intel® 64 and IA-32 Architectures Software Developer’s Manual, Volume 2B*).

These checks may be performed in any order. Thus, an indication by error number of one cause (for example, host state) does not imply that there are not also other errors. Different processors may thus give different error numbers for the same VMCS. Some checks prevent establishment of settings (or combinations of settings) that are currently reserved. Future processors may allow such settings (or combinations) and may not perform the corresponding checks. The correctness of software should not rely on VM-entry failures resulting from the checks documented in this section.

The checks on the controls and the host-state area are presented in Section 23.2.1 through Section 23.2.4. These sections reference VMCS fields that correspond to processor state. Unless otherwise stated, these references are to fields in the host-state area.

### 23.2.1 Checks on VMX Controls

This section identifies VM-entry checks on the VMX control fields.

#### 23.2.1.1 VM-Execution Control Fields

VM entries perform the following checks on the VM-execution control fields:<sup>1</sup>

- Reserved bits in the pin-based VM-execution controls must be set properly. Software may consult the VMX capability MSRs to determine the proper settings (see Appendix G.3.1).

---

1. If the “activate secondary controls” primary processor-based VM-execution control is 0, VM entry operates as if each secondary processor-based VM-execution control were 0.

## VM ENTRIES

- Reserved bits in the primary processor-based VM-execution controls must be set properly. Software may consult the VMX capability MSRs to determine the proper settings (see Appendix G.3.2).
- If the “activate secondary controls” primary processor-based VM-execution control is 1, reserved bits in the secondary processor-based VM-execution controls must be set properly. Software may consult the VMX capability MSRs to determine the proper settings (see Appendix G.3.3).  
If the “activate secondary controls” primary processor-based VM-execution control is 0 (or if the processor does not support the 1-setting of that control), no checks are performed on the secondary processor-based VM-execution controls. The logical processor operates as if all the secondary processor-based VM-execution controls were 0.
- The CR3-target count must not be greater than 4. Future processors may support a different number of CR3-target values. Software should read the VMX capability MSR IA32\_VMX\_MISC to determine the number of values supported (see Appendix G.6).
- If the “use I/O bitmaps” VM-execution control is 1, bits 11:0 of each I/O-bitmap address must be 0. Neither address should set any bits beyond the processor’s physical-address width.<sup>1,2</sup>
- If the “use MSR bitmaps” VM-execution control is 1, bits 11:0 of the MSR-bitmap address must be 0. The address should not set any bits beyond the processor’s physical-address width.<sup>3</sup>
- If the “use TPR shadow” VM-execution control is 1, the virtual-APIC address must satisfy the following checks:
  - Bits 11:0 of the address must be 0.
  - The address should not set any bits beyond the processor’s physical-address width.<sup>4</sup>

The following items describe the treatment of bytes 81H-83H on the virtual-APIC page (see Section 21.6.8) if all of the above checks are satisfied and the “use TPR shadow” VM-execution control is 1, treatment depends upon the setting of the “virtualize APIC accesses” VM-execution control:<sup>5</sup>

- If the “virtualize APIC accesses” VM-execution control is 0, the bytes may be cleared. (If the bytes are not cleared, they are left unmodified.)

- 
1. Software can determine a processor’s physical-address width by executing CPUID with 80000008H in EAX. The physical-address width is returned in bits 7:0 of EAX.
  2. If IA32\_VMX\_BASIC[48] is read as 1, these addresses must not set any bits in the range 63:32; see Appendix G.1.
  3. If IA32\_VMX\_BASIC[48] is read as 1, this address must not set any bits in the range 63:32; see Appendix G.1.
  4. If IA32\_VMX\_BASIC[48] is read as 1, this address must not set any bits in the range 63:32; see Appendix G.1.

- If the “virtualize APIC accesses” VM-execution control is 1, the bytes are cleared.
- If the VM entry fails, the any clearing of the bytes may or may not occur. This is true either if the failure causes control to pass to the instruction following the VM-entry instruction or if it cause processor state to be loaded from the host-state area of the VMCS. Behavior may be implementation-specific.
- If the “use TPR shadow” VM-execution control is 1, bits 31:4 of the TPR threshold VM-execution control field must be 0.
- The following check is performed if the “use TPR shadow” VM-execution control is 1 and the “virtualize APIC accesses” VM-execution control is 0: the value of bits 3:0 of the TPR threshold VM-execution control field should not be greater than the value of bits 7:4 in byte 80H on the virtual-APIC page (see Section 21.6.8).
- If the “NMI exiting” VM-execution control is 0, the “virtual NMIs” VM-execution control must be 0.
- If the “virtual NMIs” VM-execution control is 0, the “NMI-window exiting” VM-execution control must be 0.
- If the “virtualize APIC-accesses” VM-execution control is 1, the APIC-access address must satisfy the following checks:
  - Bits 11:0 of the address must be 0.
  - The address should not set any bits beyond the processor’s physical-address width.<sup>1</sup>
- If the “virtualize x2APIC mode” VM-execution control is 1, the “use TPR shadow” VM-execution control must be 1 and the “virtualize APIC accesses” VM-execution control must be 0.<sup>2</sup>
- If the “enable VPID” VM-execution control is 1, the value of the VPID VM-execution control field must not be 0000H.
- If the “enable EPT” VM-execution control is 1, the EPTP VM-execution control field (see Table 21-8 in Section 21.6.11) must satisfy the following checks:<sup>3</sup>

- 
5. “Virtualize APIC accesses” is a secondary processor-based VM-execution control. If bit 31 of the primary processor-based VM-execution controls is 0, VM entry functions as if the “virtualize APIC accesses” VM-execution control were 0. See Section 21.6.2.
  1. If IA32\_VMX\_BASIC[48] is read as 1, this address must not set any bits in the range 63:32; see Appendix G.1.
  2. “Virtualize APIC accesses” and “virtualize x2APIC mode” are both secondary processor-based VM-execution controls. If bit 31 of the primary processor-based VM-execution controls is 0, VM entry functions as if both these controls were 0. See Section 21.6.2.
  3. “Enable EPT” is a secondary processor-based VM-execution control. If bit 31 of the primary processor-based VM-execution controls is 0, VM entry functions as if the “enable EPT” VM-execution control were 0. See Section 21.6.2.

## VM ENTRIES

- The EPT memory type (bits 2:0) must be a value supported by the logical processor as indicated in the IA32\_VMX\_EPT\_VPID\_CAP MSR (see Appendix G.10).
- Bits 5:3 (1 less than the EPT page-walk length) must be 3, indicating an EPT page-walk length of 4; see Section 25.2.2.
- Reserved bits 11:6 and 63:N (where N is the processor’s physical-address width) must all be 0.
- If the “unrestricted guest” VM-execution control is 1, the “enable EPT” VM-execution control must also be 1.<sup>1</sup>

### 23.2.1.2 VM-Exit Control Fields

VM entries perform the following checks on the VM-exit control fields.

- Reserved bits in the VM-exit controls must be set properly. Software may consult the VMX capability MSRs to determine the proper settings (see Appendix G.4).
- If “activate VMX-preemption timer” VM-execution control is 0, the “save VMX-preemption timer value” VM-exit control must also be 0.
- The following checks are performed for the VM-exit MSR-store address if the VM-exit MSR-store count field is non-zero:
  - The lower 4 bits of the VM-exit MSR-store address must be 0. The address should not set any bits beyond the processor’s physical-address width.<sup>2</sup>
  - The address of the last byte in the VM-exit MSR-store area should not set any bits beyond the processor’s physical-address width. The address of this last byte is VM-exit MSR-store address + (MSR count \* 16) – 1. (The arithmetic used for the computation uses more bits than the processor’s physical-address width.)

If IA32\_VMX\_BASIC[48] is read as 1, neither address should set any bits in the range 63: 32; see Appendix G.1.

- The following checks are performed for the VM-exit MSR-load address if the VM-exit MSR-load count field is non-zero:
  - The lower 4 bits of the VM-exit MSR-load address must be 0. The address should not set any bits beyond the processor’s physical-address width.
  - The address of the last byte in the VM-exit MSR-load area should not set any bits beyond the processor’s physical-address width. The address of this last byte is VM-exit MSR-load address + (MSR count \* 16) – 1. (The arithmetic

- 
1. “Unrestricted guest” and “enable EPT” are both secondary processor-based VM-execution controls. If bit 31 of the primary processor-based VM-execution controls is 0, VM entry functions as if both these controls were 0. See Section 21.6.2.
  2. Software can determine a processor’s physical-address width by executing CPUID with 80000008H in EAX. The physical-address width is returned in bits 7:0 of EAX.

used for the computation uses more bits than the processor's physical-address width.)

If IA32\_VMX\_BASIC[48] is read as 1, neither address should set any bits in the range 63:32; see Appendix G.1.

### 23.2.1.3 VM-Entry Control Fields

VM entries perform the following checks on the VM-entry control fields.

- Reserved bits in the VM-entry controls must be set properly. Software may consult the VMX capability MSRs to determine the proper settings (see Appendix G.5).
- Fields relevant to VM-entry event injection must be set properly. These fields are the VM-entry interruption-information field (see Table 21-12 in Section 21.8.3), the VM-entry exception error code, and the VM-entry instruction length. If the valid bit (bit 31) in the VM-entry interruption-information field is 1, the following must hold:
  - The field's interruption type (bits 10:8) is not set to a reserved value. Value 1 is reserved on all logical processors; value 7 (other event) is reserved on logical processors that do not support the 1-setting of the "monitor trap flag" VM-execution control.
  - The field's vector (bits 7:0) is consistent with the interruption type:
    - If the interruption type is non-maskable interrupt (NMI), the vector is 2.
    - If the interruption type is hardware exception, the vector is at most 31.
    - If the interruption type is other event, the vector is 0 (pending MTF VM exit).
  - The field's deliver-error-code bit (bit 11) is 1 if and only if (1) either (a) the "unrestricted guest" VM-execution control is 0; or (b) bit 0 (corresponding to CRO.PE) is set in the CRO field in the guest-state area; (2) the interruption type is hardware exception; and (3) the vector indicates an exception that would normally deliver an error code (8 = #DF; 10 = TS; 11 = #NP; 12 = #SS; 13 = #GP; 14 = #PF; or 17 = #AC).
  - Reserved bits in the field (30:12) are 0.
  - If the deliver-error-code bit (bit 11) is 1, bits 31:15 of the VM-entry exception error-code field are 0.
  - If the interruption type is software interrupt, software exception, or privileged software exception, the VM-entry instruction-length field is in the range 1–15.
- The following checks are performed for the VM-entry MSR-load address if the VM-entry MSR-load count field is non-zero:
  - The lower 4 bits of the VM-entry MSR-load address must be 0. The address should not set any bits beyond the processor's physical-address width.<sup>1</sup>

## VM ENTRIES

- The address of the last byte in the VM-entry MSR-load area should not set any bits beyond the processor’s physical-address width. The address of this last byte is VM-entry MSR-load address + (MSR count \* 16) – 1. (The arithmetic used for the computation uses more bits than the processor’s physical-address width.)

If IA32\_VMX\_BASIC[48] is read as 1, neither address should set any bits in the range 63: 32; see Appendix G.1.

- If the processor is not in SMM, the “entry to SMM” and “deactivate dual-monitor treatment” VM-entry controls must be 0.
- The “entry to SMM” and “deactivate dual-monitor treatment” VM-entry controls cannot both be 1.

### 23.2.2 Checks on Host Control Registers and MSRs

The following checks are performed on fields in the host-state area that correspond to control registers and MSRs:

- The CRO field must not set any bit to a value not supported in VMX operation (see Section 20.8).<sup>1</sup>
- The CR4 field must not set any bit to a value not supported in VMX operation (see Section 20.8).
- On processors that support Intel 64 architecture, the CR3 field must be such that bits 63:52 and bits in the range 51:32 beyond the processor’s physical-address width must be 0.<sup>2,3</sup>
- On processors that support Intel 64 architecture, the IA32\_SYSENTER\_ESP field and the IA32\_SYSENTER\_EIP field must each contain a canonical address.
- If the “load IA32\_PERF\_GLOBAL\_CTRL” VM-exit control is 1, bits reserved in the IA32\_PERF\_GLOBAL\_CTRL MSR must be 0 in the field for that register (see Figure 30-3).
- If the “load IA32\_PAT” VM-exit control is 1, the value of the field for the IA32\_PAT MSR must be one that could be written by WRMSR without fault at CPL 0. Specifically, each of the 8 bytes in the field must have one of the values 0 (UC), 1 (WC), 4 (WT), 5 (WP), 6 (WB), or 7 (UC-).

- 
1. Software can determine a processor’s physical-address width by executing CPUID with 80000008H in EAX. The physical-address width is returned in bits 7:0 of EAX.
  1. The bits corresponding to CRO.NW (bit 29) and CRO.CD (bit 30) are never checked because the values of these bits are not changed by VM exit; see Section 24.5.1.
  2. Software can determine a processor’s physical-address width by executing CPUID with 80000008H in EAX. The physical-address width is returned in bits 7:0 of EAX.
  3. Bit 63 of the CR3 field in the host-state area must be 0. This is true even though, If CR4.PCIDE = 1, bit 63 of the source operand to MOV to CR3 is used to determine whether cached translation information is invalidated.

- If the “load IA32\_EFER” VM-exit control is 1, bits reserved in the IA32\_EFER MSR must be 0 in the field for that register. In addition, the values of the LMA and LME bits in the field must each be that of the “host address-space size” VM-exit control.

### 23.2.3 Checks on Host Segment and Descriptor-Table Registers

The following checks are performed on fields in the host-state area that correspond to segment and descriptor-table registers:

- In the selector field for each of CS, SS, DS, ES, FS, GS and TR, the RPL (bits 1:0) and the TI flag (bit 2) must be 0.
- The selector fields for CS and TR cannot be 0000H.
- The selector field for SS cannot be 0000H if the “host address-space size” VM-exit control is 0.
- On processors that support Intel 64 architecture, the base-address fields for FS, GS, GDTR, IDTR, and TR must contain canonical addresses.

### 23.2.4 Checks Related to Address-Space Size

On processors that support Intel 64 architecture, the following checks related to address-space size are performed on VMX controls and fields in the host-state area:

- If the logical processor is outside IA-32e mode (if IA32\_EFER.LMA = 0) at the time of VM entry, the following must hold:
  - The “IA-32e mode guest” VM-entry control is 0.
  - The “host address-space size” VM-exit control is 0.
- If the logical processor is in IA-32e mode (if IA32\_EFER.LMA = 1) at the time of VM entry, the “host address-space size” VM-exit control must be 1.
- If the “host address-space size” VM-exit control is 0, the following must hold:
  - The “IA-32e mode guest” VM-entry control is 0.
  - Bit 17 of the CR4 field (corresponding to CR4.PCIDE) is 0.
  - Bits 63:32 in the RIP field is 0.
- If the “host address-space size” VM-exit control is 1, the following must hold:
  - Bit 5 of the CR4 field (corresponding to CR4.PAE) is 1.
  - The RIP field contains a canonical address.

On processors that do not support Intel 64 architecture, checks are performed to ensure that the “IA-32e mode guest” VM-entry control and the “host address-space size” VM-exit control are both 0.

## 23.3 CHECKING AND LOADING GUEST STATE

If all checks on the VMX controls and the host-state area pass (see Section 23.2), the following operations take place concurrently: (1) the guest-state area of the VMCS is checked to ensure that, after the VM entry completes, the state of the logical processor is consistent with IA-32 and Intel 64 architectures; (2) processor state is loaded from the guest-state area or as specified by the VM-entry control fields; and (3) address-range monitoring is cleared.

Because the checking and the loading occur concurrently, a failure may be discovered only after some state has been loaded. For this reason, the logical processor responds to such failures by loading state from the host-state area, as it would for a VM exit. See Section 23.7.

### 23.3.1 Checks on the Guest State Area

This section describes checks performed on fields in the guest-state area. These checks may be performed in any order. Some checks prevent establishment of settings (or combinations of settings) that are currently reserved. Future processors may allow such settings (or combinations) and may not perform the corresponding checks. The correctness of software should not rely on VM-entry failures resulting from the checks documented in this section.

The following subsections reference fields that correspond to processor state. Unless otherwise stated, these references are to fields in the guest-state area.

#### 23.3.1.1 Checks on Guest Control Registers, Debug Registers, and MSRs

The following checks are performed on fields in the guest-state area corresponding to control registers, debug registers, and MSRs:

- The CRO field must not set any bit to a value not supported in VMX operation (see Section 20.8). The following are exceptions:
  - Bit 0 (corresponding to CR0.PE) and bit 31 (PG) are not checked if the “unrestricted guest” VM-execution control is 1.<sup>1</sup>
  - Bit 29 (corresponding to CR0.NW) and bit 30 (CD) are never checked because the values of these bits are not changed by VM entry; see Section 23.3.2.1.
- If bit 31 in the CRO field (corresponding to PG) is 1, bit 0 in that field (PE) must also be 1.<sup>2</sup>
- The CR4 field must not set any bit to a value not supported in VMX operation (see Section 20.8).

---

1. “Unrestricted guest” is a secondary processor-based VM-execution control. If bit 31 of the primary processor-based VM-execution controls is 0, VM entry functions as if the “unrestricted guest” VM-execution control were 0. See Section 21.6.2.

- If the “load debug controls” VM-entry control is 1, bits reserved in the IA32\_DEBUGCTL MSR must be 0 in the field for that register. The first processors to support the virtual-machine extensions supported only the 1-setting of this control and thus performed this check unconditionally.
- The following checks are performed on processors that support Intel 64 architecture:
  - If the “IA-32e mode guest” VM-entry control is 1, bit 31 in the CR0 field (corresponding to CR0.PG) and bit 5 in the CR4 field (corresponding to CR4.PAE) must each be 1.<sup>1</sup>
  - If the “IA-32e mode guest” VM-entry control is 0, bit 17 in the CR4 field (corresponding to CR4.PCIDE) must each be 0.
  - The CR3 field must be such that bits 63:52 and bits in the range 51:32 beyond the processor’s physical-address width are 0.<sup>2,3</sup>
  - If the “load debug controls” VM-entry control is 1, bits 63:32 in the DR7 field must be 0. The first processors to support the virtual-machine extensions supported only the 1-setting of this control and thus performed this check unconditionally (if they supported Intel 64 architecture).
  - The IA32\_SYSENTER\_ESP field and the IA32\_SYSENTER\_EIP field must each contain a canonical address.
- If the “load IA32\_PERF\_GLOBAL\_CTRL” VM-entry control is 1, bits reserved in the IA32\_PERF\_GLOBAL\_CTRL MSR must be 0 in the field for that register (see Figure 30-3).
- If the “load IA32\_PAT” VM-entry control is 1, the value of the field for the IA32\_PAT MSR must be one that could be written by WRMSR without fault at CPL 0. Specifically, each of the 8 bytes in the field must have one of the values 0 (UC), 1 (WC), 4 (WT), 5 (WP), 6 (WB), or 7 (UC-).
- If the “load IA32\_EFER” VM-entry control is 1, the following checks are performed on the field for the IA32\_EFER MSR :
  - Bits reserved in the IA32\_EFER MSR must be 0.

- 
- 2. If the capability MSR IA32\_VMX\_CRO\_FIXED0 reports that CRO.PE must be 1 in VMX operation, bit 0 in the CRO field must be 1 unless the “unrestricted guest” VM-execution control and bit 31 of the primary processor-based VM-execution controls are both 1.
  - 1. If the capability MSR IA32\_VMX\_CRO\_FIXED0 reports that CRO.PG must be 1 in VMX operation, bit 31 in the CRO field must be 1 unless the “unrestricted guest” VM-execution control and bit 31 of the primary processor-based VM-execution controls are both 1.
  - 2. Software can determine a processor’s physical-address width by executing CPUID with 80000008H in EAX. The physical-address width is returned in bits 7:0 of EAX.
  - 3. Bit 63 of the CR3 field in the guest-state area must be 0. This is true even though, If CR4.PCIDE = 1, bit 63 of the source operand to MOV to CR3 is used to determine whether cached translation information is invalidated.

## VM ENTRIES

- Bit 10 (corresponding to IA32\_EFER.LMA) must equal the value of the “IA-32e mode guest” VM-exit control. It must also be identical to bit 8 (LME) if bit 31 in the CRO field (corresponding to CRO.PG) is 1.<sup>1</sup>

### 23.3.1.2 Checks on Guest Segment Registers

This section specifies the checks on the fields for CS, SS, DS, ES, FS, GS, TR, and LDTR. The following terms are used in defining these checks:

- The guest will be **virtual-8086** if the VM flag (bit 17) is 1 in the RFLAGS field in the guest-state area.
- The guest will be **IA-32e mode** if the “IA-32e mode guest” VM-entry control is 1. (This is possible only on processors that support Intel 64 architecture.)
- Any one of these registers is said to be **usable** if the unusable bit (bit 16) is 0 in the access-rights field for that register.

The following are the checks on these fields:

- Selector fields.
  - TR. The TI flag (bit 2) must be 0.
  - LDTR. If LDTR is usable, the TI flag (bit 2) must be 0.
  - SS. If the guest will not be virtual-8086 and the “unrestricted guest” VM-execution control is 0, the RPL (bits 1:0) must equal the RPL of the selector field for CS.<sup>2</sup>
- Base-address fields.
  - CS, SS, DS, ES, FS, GS. If the guest will be virtual-8086, the address must be the selector field shifted left 4 bits (multiplied by 16).
  - The following checks are performed on processors that support Intel 64 architecture:
    - TR, FS, GS. The address must be canonical.
    - LDTR. If LDTR is usable, the address must be canonical.
    - CS. Bits 63:32 of the address must be zero.
    - SS, DS, ES. If the register is usable, bits 63:32 of the address must be zero.
- Limit fields for CS, SS, DS, ES, FS, GS. If the guest will be virtual-8086, the field must be 0000FFFFH.

- 
1. If the capability MSR IA32\_VMX\_CRO\_FIXED0 reports that CRO.PG must be 1 in VMX operation, bit 31 in the CRO field must be 1 unless the “unrestricted guest” VM-execution control and bit 31 of the primary processor-based VM-execution controls are both 1.
  2. “Unrestricted guest” is a secondary processor-based VM-execution control. If bit 31 of the primary processor-based VM-execution controls is 0, VM entry functions as if the “unrestricted guest” VM-execution control were 0. See Section 21.6.2.

- Access-rights fields.
  - CS, SS, DS, ES, FS, GS.
  - If the guest will be virtual-8086, the field must be 000000F3H. This implies the following:
    - Bits 3:0 (Type) must be 3, indicating an expand-up read/write accessed data segment.
    - Bit 4 (S) must be 1.
    - Bits 6:5 (DPL) must be 3.
    - Bit 7 (P) must be 1.
    - Bits 11:8 (reserved), bit 12 (software available), bit 13 (reserved/L), bit 14 (D/B), bit 15 (G), bit 16 (unusable), and bits 31:17 (reserved) must all be 0.
  - If the guest will not be virtual-8086, the different sub-fields are considered separately:
    - Bits 3:0 (Type).
      - CS. The values allowed depend on the setting of the “unrestricted guest” VM-execution control:
        - If the control is 0, the Type must be 9, 11, 13, or 15 (accessed code segment).
        - If the control is 1, the Type must be either 3 (read/write accessed expand-up data segment) or one of 9, 11, 13, and 15 (accessed code segment).
      - SS. If SS is usable, the Type must be 3 or 7 (read/write, accessed data segment).
      - DS, ES, FS, GS. The following checks apply if the register is usable:
        - Bit 0 of the Type must be 1 (accessed).
        - If bit 3 of the Type is 1 (code segment), then bit 1 of the Type must be 1 (readable).
    - Bit 4 (S). If the register is CS or if the register is usable, S must be 1.
    - Bits 6:5 (DPL).
      - CS.
        - If the Type is 3 (read/write accessed expand-up data segment), the DPL must be 0. The Type can be 3 only if the “unrestricted guest” VM-execution control is 1.
        - If the Type is 9 or 11 (non-conforming code segment), the DPL must equal the DPL in the access-rights field for SS.

## VM ENTRIES

- If the Type is 13 or 15 (conforming code segment), the DPL cannot be greater than the DPL in the access-rights field for SS.
- SS.
  - If the “unrestricted guest” VM-execution control is 0, the DPL must equal the RPL from the selector field.
  - The DPL must be 0 either if the Type in the access-rights field for CS is 3 (read/write accessed expand-up data segment) or if bit 0 in the CRO field (corresponding to CRO.PE) is 0.<sup>1</sup>
- DS, ES, FS, GS. The DPL cannot be less than the RPL in the selector field if (1) the “unrestricted guest” VM-execution control is 0; (2) the register is usable; and (3) the Type in the access-rights field is in the range 0 – 11 (data segment or non-conforming code segment).
- Bit 7 (P). If the register is CS or if the register is usable, P must be 1.
- Bits 11:8 (reserved). If the register is CS or if the register is usable, these bits must all be 0.
- Bit 14 (D/B). For CS, D/B must be 0 if the guest will be IA-32e mode and the L bit (bit 13) in the access-rights field is 1.
- Bit 15 (G). The following checks apply if the register is CS or if the register is usable:
  - If any bit in the limit field in the range 11:0 is 0, G must be 0.
  - If any bit in the limit field in the range 31:20 is 1, G must be 1.
- Bits 31:17 (reserved). If the register is CS or if the register is usable, these bits must all be 0.
- TR. The different sub-fields are considered separately:
  - Bits 3:0 (Type).
    - If the guest will not be IA-32e mode, the Type must be 3 (16-bit busy TSS) or 11 (32-bit busy TSS).
    - If the guest will be IA-32e mode, the Type must be 11 (64-bit busy TSS).
  - Bit 4 (S). S must be 0.
  - Bit 7 (P). P must be 1.
  - Bits 11:8 (reserved). These bits must all be 0.

---

1. The following apply if either the “unrestricted guest” VM-execution control or bit 31 of the primary processor-based VM-execution controls is 0: (1) bit 0 in the CRO field must be 1 if the capability MSR IA32\_VMX\_CRO\_FIXED0 reports that CRO.PE must be 1 in VMX operation; and (2) the Type in the access-rights field for CS cannot be 3.

- Bit 15 (G).
  - If any bit in the limit field in the range 11:0 is 0, G must be 0.
  - If any bit in the limit field in the range 31:20 is 1, G must be 1.
- Bit 16 (Unusable). The unusable bit must be 0.
- Bits 31:17 (reserved). These bits must all be 0.
- LDTR. The following checks on the different sub-fields apply only if LDTR is usable:
  - Bits 3:0 (Type). The Type must be 2 (LDT).
  - Bit 4 (S). S must be 0.
  - Bit 7 (P). P must be 1.
  - Bits 11:8 (reserved). These bits must all be 0.
  - Bit 15 (G).
    - If any bit in the limit field in the range 11:0 is 0, G must be 0.
    - If any bit in the limit field in the range 31:20 is 1, G must be 1.
  - Bits 31:17 (reserved). These bits must all be 0.

### 23.3.1.3 Checks on Guest Descriptor-Table Registers

The following checks are performed on the fields for GDTR and IDTR:

- On processors that support Intel 64 architecture, the base-address fields must contain canonical addresses.
- Bits 31:16 of each limit field must be 0.

### 23.3.1.4 Checks on Guest RIP and RFLAGS

The following checks are performed on fields in the guest-state area corresponding to RIP and RFLAGS:

- RIP. The following checks are performed on processors that support Intel 64 architecture:
  - Bits 63:32 must be 0 if the “IA-32e mode guest” VM-entry control is 0 or if the L bit (bit 13) in the access-rights field for CS is 0.
  - If the processor supports  $N < 64$  linear-address bits, bits 63:N must be identical if the “IA-32e mode guest” VM-entry control is 1 and the L bit in the access-rights field for CS is 1.<sup>1</sup> (No check applies if the processor supports 64 linear-address bits.)

---

1. Software can determine the number N by executing CPUID with 80000008H in EAX. The number of linear-address bits supported is returned in bits 15:8 of EAX.

## VM ENTRIES

- RFLAGS.
  - Reserved bits 63:22 (bits 31:22 on processors that do not support Intel 64 architecture), bit 15, bit 5 and bit 3 must be 0 in the field, and reserved bit 1 must be 1.
  - The VM flag (bit 17) must be 0 either if the “IA-32e mode guest” VM-entry control is 1 or if bit 0 in the CRO field (corresponding to CRO.PE) is 0.<sup>1</sup>
  - The IF flag (RFLAGS[bit 9]) must be 1 if the valid bit (bit 31) in the VM-entry interruption-information field is 1 and the interruption type (bits 10:8) is external interrupt.

### 23.3.1.5 Checks on Guest Non-Register State

The following checks are performed on fields in the guest-state area corresponding to non-register state:

- Activity state.
  - The activity-state field must contain a value in the range 0 – 3, indicating an activity state supported by the implementation (see Section 21.4.2). Future processors may include support for other activity states. Software should read the VMX capability MSR IA32\_VMX\_MISC (see Appendix G.6) to determine what activity states are supported.
  - The activity-state field must not indicate the HLT state if the DPL (bits 6:5) in the access-rights field for SS is not 0.<sup>2</sup>
  - The activity-state field must indicate the active state if the interruptibility-state field indicates blocking by either MOV-SS or by STI (if either bit 0 or bit 1 in that field is 1).
  - If the valid bit (bit 31) in the VM-entry interruption-information field is 1, the interruption to be delivered (as defined by interruption type and vector) must not be one that would normally be blocked while a logical processor is in the activity state corresponding to the contents of the activity-state field. The following items enumerate the interruptions (as specified in the VM-entry interruption-information field) whose injection is allowed for the different activity states:
    - Active. Any interruption is allowed.
    - HLT. The only events allowed are the following:

- 
1. If the capability MSR IA32\_VMX\_CRO\_FIXED0 reports that CRO.PE must be 1 in VMX operation, bit 0 in the CRO field must be 1 unless the “unrestricted guest” VM-execution control and bit 31 of the primary processor-based VM-execution controls are both 1.
  2. As noted in Section 21.4.1, SS.DPL corresponds to the logical processor’s current privilege level (CPL).

- Those with interruption type external interrupt or non-maskable interrupt (NMI).
- Those with interruption type hardware exception and vector 1 (debug exception) or vector 18 (machine-check exception).
- Those with interruption type other event and vector 0 (pending MTF VM exit).

See Table 21-12 in Section 21.8.3 for details regarding the format of the VM-entry interruption-information field.

- Shutdown. Only NMIs and machine-check exceptions are allowed.
- Wait-for-SIPI. No interruptions are allowed.
- The activity-state field must not indicate the wait-for-SIPI state if the “entry to SMM” VM-entry control is 1.
- Interruptibility state.
  - The reserved bits (bits 31:4) must be 0.
  - The field cannot indicate blocking by both STI and MOV SS (bits 0 and 1 cannot both be 1).
  - Bit 0 (blocking by STI) must be 0 if the IF flag (bit 9) is 0 in the RFLAGS field.
  - Bit 0 (blocking by STI) and bit 1 (blocking by MOV-SS) must both be 0 if the valid bit (bit 31) in the VM-entry interruption-information field is 1 and the interruption type (bits 10:8) in that field has value 0, indicating external interrupt.
  - Bit 1 (blocking by MOV-SS) must be 0 if the valid bit (bit 31) in the VM-entry interruption-information field is 1 and the interruption type (bits 10:8) in that field has value 2, indicating non-maskable interrupt (NMI).
  - Bit 2 (blocking by SMI) must be 0 if the processor is not in SMM.
  - Bit 2 (blocking by SMI) must be 1 if the “entry to SMM” VM-entry control is 1.
  - A processor may require bit 0 (blocking by STI) to be 0 if the valid bit (bit 31) in the VM-entry interruption-information field is 1 and the interruption type (bits 10:8) in that field has value 2, indicating NMI. Other processors may not make this requirement.
  - Bit 3 (blocking by NMI) must be 0 if the “virtual NMIs” VM-execution control is 1, the valid bit (bit 31) in the VM-entry interruption-information field is 1, and the interruption type (bits 10:8) in that field has value 2 (indicating NMI).

#### NOTE

If the “virtual NMIs” VM-execution control is 0, there is no requirement that bit 3 be 0 if the valid bit in the VM-entry interruption-information field is 1 and the interruption type in that field has value 2.

## VM ENTRIES

- Pending debug exceptions.
  - Bits 11:4, bit 13, and bits 63:15 (bits 31:15 on processors that do not support Intel 64 architecture) must be 0.
  - The following checks are performed if any of the following holds: (1) the interruptibility-state field indicates blocking by STI (bit 0 in that field is 1); (2) the interruptibility-state field indicates blocking by MOV SS (bit 1 in that field is 1); or (3) the activity-state field indicates HLT:
    - Bit 14 (BS) must be 1 if the TF flag (bit 8) in the RFLAGS field is 1 and the BTF flag (bit 1) in the IA32\_DEBUGCTL field is 0.
    - Bit 14 (BS) must be 0 if the TF flag (bit 8) in the RFLAGS field is 0 or the BTF flag (bit 1) in the IA32\_DEBUGCTL field is 1.
- VMCS link pointer. The following checks apply if the field contains a value other than FFFFFFFF\_FFFFFFFFH:
  - Bits 11:0 must be 0.
  - Bits beyond the processor’s physical-address width must be 0.<sup>1,2</sup>
  - The 32 bits located in memory referenced by the value of the field (as a physical address) must contain the processor’s VMCS revision identifier (see Section 21.2).
  - If the processor is not in SMM or the “entry to SMM” VM-entry control is 1, the field must not contain the current VMCS pointer.
  - If the processor is in SMM and the “entry to SMM” VM-entry control is 0, the field must not contain the VMXON pointer.

### 23.3.1.6 Checks on Guest Page-Directory-Pointer-Table Entries

If CRO.PG = 1, CR4.PAE = 1, and IA32\_EFER.LMA = 0, the logical processor also uses **PAE paging** (see Section 4.4 in the *Intel® 64 and IA-32 Architectures Software Developer’s Manual, Volume 3A*).<sup>3</sup> When PAE paging is in use, the physical address in CR3 references a table of **page-directory-pointer-table entries** (PDPTes). A MOV to CR3 when PAE paging is in use checks the validity of the PDPTes.

A VM entry is to a guest that uses PAE paging if (1) bit 31 (corresponding to CRO.PG) is set in the CRO field in the guest-state area; (2) bit 5 (corresponding to CR4.PAE) is

- 
1. Software can determine a processor’s physical-address width by executing CPUID with 80000008H in EAX. The physical-address width is returned in bits 7:0 of EAX.
  2. If IA32\_VMX\_BASIC[48] is read as 1, this field must not set any bits in the range 63:32; see Appendix G.1.
  3. On processors that support Intel 64 architecture, the physical-address extension may support more than 36 physical-address bits. Software can determine the number physical-address bits supported by executing CPUID with 80000008H in EAX. The physical-address width is returned in bits 7:0 of EAX.

set in the CR4 field; and (3) the “IA-32e mode guest” VM-entry control is 0. Such a VM entry checks the validity of the PDPTEs:

- If the “enable EPT” VM-execution control is 0, VM entry checks the validity of the PDPTEs referenced by the CR3 field in the guest-state area if either (1) PAE paging was not in use before the VM entry; or (2) the value of CR3 is changing as a result of the VM entry. VM entry may check their validity even if neither (1) nor (2) hold.<sup>1</sup>
- If the “enable EPT” VM-execution control is 1, VM entry checks the validity of the PDPTE fields in the guest-state area (see Section 21.4.2).

A VM entry to a guest that does not use PAE paging does not check the validity of any PDPTEs.

A VM entry that checks the validity of the PDPTEs uses the same checks that are used when CR3 is loaded with MOV to CR3 when PAE paging is in use.<sup>2</sup> If MOV to CR3 would cause a general-protection exception due to the PDPTEs that would be loaded (e.g., because a reserved bit is set), the VM entry fails.

### 23.3.2 Loading Guest State

Processor state is updated on VM entries in the following ways:

- Some state is loaded from the guest-state area.
- Some state is determined by VM-entry controls.
- The page-directory pointers are loaded based on the values of certain control registers.

This loading may be performed in any order and in parallel with the checking of VMCS contents (see Section 23.3.1).

The loading of guest state is detailed in Section 23.3.2.1 to Section 23.3.2.4. These sections reference VMCS fields that correspond to processor state. Unless otherwise stated, these references are to fields in the guest-state area.

In addition to the state loading described in this section, VM entries may load MSRs from the VM-entry MSR-load area (see Section 23.4). This loading occurs only after the state loading described in this section and the checking of VMCS contents described in Section 23.3.1.

- 
1. “Enable EPT” is a secondary processor-based VM-execution control. If bit 31 of the primary processor-based VM-execution controls is 0, VM entry functions as if the “enable EPT” VM-execution control were 0. See Section 21.6.2.
  2. This implies that (1) bits 11:9 in each PDPTE are ignored; and (2) if bit 0 (present) is clear in one of the PDPTEs, bits 63:1 of that PDPTE are ignored.

### 23.3.2.1 Loading Guest Control Registers, Debug Registers, and MSRs

The following items describe how guest control registers, debug registers, and MSRs are loaded on VM entry:

- CRO is loaded from the CRO field with the exception of the following bits, which are never modified on VM entry: ET (bit 4); reserved bits 15:6, 17, and 28:19; NW (bit 29) and CD (bit 30).<sup>1</sup> The values of these bits in the CRO field are ignored.
- CR3 and CR4 are loaded from the CR3 field and the CR4 field, respectively.
- If the “load debug controls” VM-execution control is 1, DR7 is loaded from the DR7 field with the exception that bit 12 and bits 15:14 are always 0 and bit 10 is always 1. The values of these bits in the DR7 field are ignored.

The first processors to support the virtual-machine extensions supported only the 1-setting of the “load debug controls” VM-execution control and thus always loaded DR7 from the DR7 field.

- The following describes how some MSRs are loaded using fields in the guest-state area:
  - If the “load debug controls” VM-execution control is 1, the IA32\_DEBUGCTL MSR is loaded from the IA32\_DEBUGCTL field. The first processors to support the virtual-machine extensions supported only the 1-setting of this control and thus always loaded the IA32\_DEBUGCTL MSR from the IA32\_DEBUGCTL field.
  - The IA32\_SYSENTER\_CS MSR is loaded from the IA32\_SYSENTER\_CS field. Since this field has only 32 bits, bits 63:32 of the MSR are cleared to 0.
  - The IA32\_SYSENTER\_ESP and IA32\_SYSENTER\_EIP MSRs are loaded from the IA32\_SYSENTER\_ESP field and the IA32\_SYSENTER\_EIP field, respectively. On processors that do not support Intel 64 architecture, these fields have only 32 bits; bits 63:32 of the MSRs are cleared to 0.
  - The following are performed on processors that support Intel 64 architecture:
    - The MSRs FS.base and GS.base are loaded from the base-address fields for FS and GS, respectively (see Section 23.3.2.2).
    - If the “load IA32\_EFER” VM-entry control is 0, bits in the IA32\_EFER MSR are modified as follows:
      - IA32\_EFER.LMA is loaded with the setting of the “IA-32e mode guest” VM-entry control.
      - If CR0 is being loaded so that CR0.PG = 1, IA32\_EFER.LME is also loaded with the setting of the “IA-32e mode guest” VM-entry control.<sup>2</sup> Otherwise, IA32\_EFER.LME is unmodified.

---

1. Bits 15:6, bit 17, and bit 28:19 of CRO and CRO.ET are unchanged by executions of MOV to CRO. Bits 15:6, bit 17, and bit 28:19 of CRO are always 0 and CRO.ET is always 1.

See below for the case in which the “load IA32\_EFER” VM-entry control is 1

- If the “load IA32\_PERF\_GLOBAL\_CTRL” VM-entry control is 1, the IA32\_PERF\_GLOBAL\_CTRL MSR is loaded from the IA32\_PERF\_GLOBAL\_CTRL field.
- If the “load IA32\_PAT” VM-entry control is 1, the IA32\_PAT MSR is loaded from the IA32\_PAT field.
- If the “load IA32\_EFER” VM-entry control is 1, the IA32\_EFER MSR is loaded from the IA32\_EFER field.

With the exception of FS.base and GS.base, any of these MSRs is subsequently overwritten if it appears in the VM-entry MSR-load area. See Section 23.4.

- The SMBASE register is unmodified by all VM entries except those that return from SMM.

### 23.3.2.2 Loading Guest Segment Registers and Descriptor-Table Registers

For each of CS, SS, DS, ES, FS, GS, TR, and LDTR, fields are loaded from the guest-state area as follows:

- The unusable bit is loaded from the access-rights field. This bit can never be set for TR (see Section 23.3.1.2). If it is set for one of the other registers, the following apply:
  - For each of CS, SS, DS, ES, FS, and GS, uses of the segment cause faults (general-protection exception or stack-fault exception) outside 64-bit mode, just as they would had the segment been loaded using a null selector. This bit does not cause accesses to fault in 64-bit mode.
  - If this bit is set for LDTR, uses of LDTR cause general-protection exceptions in all modes, just as they would had LDTR been loaded using a null selector.

If this bit is clear for any of CS, SS, DS, ES, FS, GS, TR, and LDTR, a null selector value does not cause a fault (general-protection exception or stack-fault exception).

- TR. The selector, base, limit, and access-rights fields are loaded.
- CS.
  - The following fields are always loaded: selector, base address, limit, and (from the access-rights field) the L, D, and G bits.
  - For the other fields, the unusable bit of the access-rights field is consulted:
    - If the unusable bit is 0, all of the access-rights field is loaded.

- 
2. If the capability MSR IA32\_VMX\_CRO\_FIXED0 reports that CRO.PG must be 1 in VMX operation, VM entry must be loading CRO so that CRO.PG = 1 unless the “unrestricted guest” VM-execution control and bit 31 of the primary processor-based VM-execution controls are both 1.

## VM ENTRIES

- If the unusable bit is 1, the remainder of CS access rights are undefined after VM entry.
- SS, DS, ES, FS, GS, and LDTR.
  - The selector fields are loaded.
  - For the other fields, the unusable bit of the corresponding access-rights field is consulted:
    - If the unusable bit is 0, the base-address, limit, and access-rights fields are loaded.
    - If the unusable bit is 1, the base address, the segment limit, and the remainder of the access rights are undefined after VM entry with the following exceptions:
      - Bits 3:0 of the base address for SS are cleared to 0.
      - SS.DPL is always loaded from the SS access-rights field. This will be the current privilege level (CPL) after the VM entry completes.
      - SS.B is always set to 1.
      - The base addresses for FS and GS are loaded from the corresponding fields in the VMCS. On processors that support Intel 64 architecture, the values loaded for base addresses for FS and GS are also manifest in the FS.base and GS.base MSRs.
      - On processors that support Intel 64 architecture, the base address for LDTR is set to an undefined but canonical value.
      - On processors that support Intel 64 architecture, bits 63:32 of the base addresses for SS, DS, and ES are cleared to 0.

GDTR and IDTR are loaded using the base and limit fields.

### 23.3.2.3 Loading Guest RIP, RSP, and RFLAGS

RSP, RIP, and RFLAGS are loaded from the RSP field, the RIP field, and the RFLAGS field, respectively. The following items regard the upper 32 bits of these fields on VM entries that are not to 64-bit mode:

- Bits 63:32 of RSP are undefined outside 64-bit mode. Thus, a logical processor may ignore the contents of bits 63:32 of the RSP field on VM entries that are not to 64-bit mode.
- As noted in Section 23.3.1.4, bits 63:32 of the RIP and RFLAGS fields must be 0 on VM entries that are not to 64-bit mode.

### 23.3.2.4 Loading Page-Directory-Pointer-Table Entries

As noted in Section 23.3.1.6, the logical processor uses PAE paging if bit 5 in CR4 (CR4.PAE) is 1 and IA32\_EFER.LMA is 0. A VM entry to a guest that uses PAE paging

loads the PDPTEs into internal, non-architectural registers based on the setting of the “enable EPT” VM-execution control:

- If the control is 0, the PDPTEs are loaded from the page-directory-pointer table referenced by the physical address in the value of CR3 being loaded by the VM entry (see Section 23.3.2.1). The values loaded are treated as physical addresses in VMX non-root operation.
- If the control is 1, the PDPTEs are loaded from corresponding fields in the guest-state area (see Section 21.4.2). The values loaded are treated as guest-physical addresses in VMX non-root operation.

### 23.3.2.5 Updating Non-Register State

Section 25.3 describe how the VMX architecture controls how a logical processor manages information in the TLBs and paging-structure caches. The following items detail how VM entries invalidate cached mappings:

- If the “enable VPID” VM-execution control is 0, the logical processor invalidates linear mappings and combined mappings associated with VPID 0000H (for all PCIDs); combined mappings for VPID 0000H are invalidated for all EP4TA values (EP4TA is the value of bits 51:12 of EPTP).
- VM entries are not required to invalidate any guest-physical mappings, nor are they required to invalidate any linear mappings or combined mappings if the “enable VPID” VM-execution control is 1.

### 23.3.3 Clearing Address-Range Monitoring

The Intel 64 and IA-32 architectures allow software to monitor a specified address range using the MONITOR and MWAIT instructions. See Section 8.10.4 in the *Intel® 64 and IA-32 Architectures Software Developer’s Manual, Volume 3A*. VM entries clear any address-range monitoring that may be in effect.

## 23.4 LOADING MSRS

VM entries may load MSRs from the VM-entry MSR-load area (see Section 21.8.2). Specifically each entry in that area (up to the number specified in the VM-entry MSR-load count) is processed in order by loading the MSR indexed by bits 31:0 with the contents of bits 127:64 as they would be written by WRMSR.<sup>1</sup>

Processing of an entry fails in any of the following cases:

- The value of bits 31:0 is either C0000100H (the IA32\_FS\_BASE MSR) or C0000101 (the IA32\_GS\_BASE MSR).

---

1. Because attempts to modify the value of IA32\_EFER.LMA by WRMSR are ignored, attempts to modify it using the VM-entry MSR-load area are also ignored.

## VM ENTRIES

- The value of bits 31:8 is 000008H, meaning that the indexed MSR is one that allows access to an APIC register when the local APIC is in x2APIC mode.
- The value of bits 31:0 indicates an MSR that can be written only in system-management mode (SMM) and the VM entry did not commence in SMM. (IA32\_SMM\_MONITOR\_CTL is an MSR that can be written only in SMM.)
- The value of bits 31:0 indicates an MSR that cannot be loaded on VM entries for model-specific reasons. A processor may prevent loading of certain MSRs even if they can normally be written by WRMSR. Such model-specific behavior is documented in Appendix B.
- Bits 63:32 are not all 0.
- An attempt to write bits 127:64 to the MSR indexed by bits 31:0 of the entry would cause a general-protection exception if executed via WRMSR with CPL = 0.<sup>1</sup>

The VM entry fails if processing fails for any entry. The logical processor responds to such failures by loading state from the host-state area, as it would for a VM exit. See Section 23.7.

If any MSR is being loaded in such a way that would architecturally require a TLB flush, the TLBs are updated so that, after VM entry, the logical processor will not use any translations that were cached before the transition.

## 23.5 EVENT INJECTION

If the valid bit in the VM-entry interruption-information field (see Section 21.8.3) is 1, VM entry causes an event to be delivered (or made pending) after all components of guest state have been loaded (including MSRs) and after the VM-execution control fields have been established.

- If the interruption type in the field is 0 (external interrupt), 2 (non-maskable interrupt); 3 (hardware exception), 4 (software interrupt), 5 (privileged software exception), or 6 (software exception), the event is delivered as described in Section 23.5.1.
- If the interruption type in the field is 7 (other event) and the vector field is 0, an MTF VM exit is pending after VM entry. See Section 23.5.2.

### 23.5.1 Vectored-Event Injection

VM entry delivers an injected vectored event within the guest context established by VM entry. This means that delivery occurs after all components of guest state have

---

1. If CRO.PG = 1, WRMSR to the IA32\_EFER MSR causes a general-protection exception if it would modify the LME bit. If VM entry has established CRO.PG = 1, the IA32\_EFER MSR should not be included in the VM-entry MSR-load area for the purpose of modifying the LME bit.

been loaded (including MSRs) and after the VM-execution control fields have been established.<sup>1</sup> The event is delivered using the vector in that field to select a descriptor in the IDT. Since event injection occurs after loading IDTR from the guest-state area, this is the guest IDT.

Section 23.5.1.1 provides details of vectored-event injection. In general, the event is delivered exactly as if it had been generated normally.

If event delivery encounters a nested exception (for example, a general-protection exception because the vector indicates a descriptor beyond the IDT limit), the exception bitmap is consulted using the vector of that exception. If the bit is 0, the exception is delivered through the IDT. If the bit is 1, a VM exit occurs. Section 23.5.1.2 details cases in which event injection causes a VM exit.

### 23.5.1.1 Details of Vectored-Event Injection

The event-injection process is controlled by the contents of the VM-entry interruption information field (format given in Table 21-12), the VM-entry exception error-code field, and the VM-entry instruction-length field. The following items provide details of the process:

- The value pushed on the stack for RFLAGS is generally that which was loaded from the guest-state area. The value pushed for the RF flag is not modified based on the type of event being delivered. However, the pushed value of RFLAGS may be modified if a software interrupt is being injected into a guest that will be in virtual-8086 mode (see below). After RFLAGS is pushed on the stack, the value in the RFLAGS register is modified as is done normally when delivering an event through the IDT.
- The instruction pointer that is pushed on the stack depends on the type of event and whether nested exceptions occur during its delivery. The term **current guest RIP** refers to the value to be loaded from the guest-state area. The value pushed is determined as follows:<sup>2</sup>
  - If VM entry successfully injects (with no nested exception) an event with interruption type external interrupt, NMI, or hardware exception, the current guest RIP is pushed on the stack.
  - If VM entry successfully injects (with no nested exception) an event with interruption type software interrupt, privileged software exception, or software exception, the current guest RIP is incremented by the VM-entry instruction length before being pushed on the stack.

- 
1. This does not imply that injection of an exception or interrupt will cause a VM exit due to the settings of VM-execution control fields (such as the exception bitmap) that would cause a VM exit if the event had occurred in VMX non-root operation. In contrast, a nested exception encountered during event delivery may cause a VM exit; see Section 23.5.1.1.
  2. While these items refer to RIP, the width of the value pushed (16 bits, 32 bits, or 64 bits) is determined normally.

## VM ENTRIES

- If VM entry encounters an exception while injecting an event and that exception does not cause a VM exit, the current guest RIP is pushed on the stack regardless of event type or VM-entry instruction length. If the encountered exception does cause a VM exit that saves RIP, the saved RIP is current guest RIP.
  - If the deliver-error-code bit (bit 11) is set in the VM-entry interruption-information field, the contents of the VM-entry exception error-code field is pushed on the stack as an error code would be pushed during delivery of an exception.
  - DR6, DR7, and the IA32\_DEBUGCTL MSR are not modified by event injection, even if the event has vector 1 (normal deliveries of debug exceptions, which have vector 1, do update these registers).
  - If VM entry is injecting a software interrupt and the guest will be in virtual-8086 mode (RFLAGS.VM = 1), no general-protection exception can occur due to RFLAGS.IOPL < 3. A VM monitor should check RFLAGS.IOPL before injecting such an event and, if desired, inject a general-protection exception instead of a software interrupt.
  - If VM entry is injecting a software interrupt and the guest will be in virtual-8086 mode with virtual-8086 mode extensions (RFLAGS.VM = CR4.VME = 1), event delivery is subject to VME-based interrupt redirection based on the software interrupt redirection bitmap in the task-state segment (TSS) as follows:
    - If bit  $n$  in the bitmap is clear (where  $n$  is the number of the software interrupt), the interrupt is directed to an 8086 program interrupt handler: the processor uses a 16-bit interrupt-vector table (IVT) located at linear address zero. If the value of RFLAGS.IOPL is less than 3, the following modifications are made to the value of RFLAGS that is pushed on the stack: IOPL is set to 3, and IF is set to the value of VIF.
    - If bit  $n$  in the bitmap is set (where  $n$  is the number of the software interrupt), the interrupt is directed to a protected-mode interrupt handler. (In other words, the injection is treated as described in the next item.) In this case, the software interrupt does not invoke such a handler if RFLAGS.IOPL < 3 (a general-protection exception occurs instead). However, as noted above, RFLAGS.IOPL cannot cause an injected software interrupt to cause such a exception. Thus, in this case, the injection invokes a protected-mode interrupt handler independent of the value of RFLAGS.IOPL.
- Injection of events of other types are not subject to this redirection.
- If VM entry is injecting a software interrupt (not redirected as described above) or software exception, privilege checking is performed on the IDT descriptor being accessed as would be the case for executions of INT  $n$ , INT3, or INTO (the descriptor's DPL cannot be less than CPL). There is no checking of RFLAGS.IOPL, even if the guest will be in virtual-8086 mode. Failure of this check may lead to a nested exception. Injection of an event with interruption type external interrupt, NMI, hardware exception, and privileged software exception, or with interruption

type software interrupt and being redirected as described above, do not perform these checks.

- If VM entry is injecting a non-maskable interrupt (NMI) and the “virtual NMIs” VM-execution control is 1, virtual-NMI blocking is in effect after VM entry.
- The transition causes a last-branch record to be logged if the LBR bit is set in the IA32\_DEBUGCTL MSR. This is true even for events such as debug exceptions, which normally clear the LBR bit before delivery.
- The last-exception record MSRs (LERs) may be updated based on the setting of the LBR bit in the IA32\_DEBUGCTL MSR. Events such as debug exceptions, which normally clear the LBR bit before they are delivered, and therefore do not normally update the LERs, may do so as part of VM-entry event injection.
- If injection of an event encounters a nested exception that does not itself cause a VM exit, the value of the EXT bit (bit 0) in any error code pushed on the stack is determined as follows:
  - If event being injected has interruption type external interrupt, NMI, hardware exception, or privileged software exception and encounters a nested exception (but does not produce a double fault), the error code for the first such exception encountered sets the EXT bit.
  - If event being injected is a software interrupt or an software exception and encounters a nested exception (but does not produce a double fault), the error code for the first such exception encountered clears the EXT bit.
  - If event delivery encounters a nested exception and delivery of that exception encounters another exception (but does not produce a double fault), the error code for that exception sets the EXT bit. If a double fault is produced, the error code for the double fault is 0000H (the EXT bit is clear).

### 23.5.1.2 VM Exits During Event Injection

An event being injected never causes a VM exit directly regardless of the settings of the VM-execution controls. For example, setting the “NMI exiting” VM-execution control to 1 does not cause a VM exit due to injection of an NMI.

However, the event-delivery process may lead to a VM exit:

- If the vector in the VM-entry interruption-information field identifies a task gate in the IDT, the attempted task switch may cause a VM exit just as it would had the injected event occurred during normal execution in VMX non-root operation (see Section 22.6.2).
- If event delivery encounters a nested exception, a VM exit may occur depending on the contents of the exception bitmap (see Section 22.3).
- If event delivery generates a double-fault exception (due to a nested exception); the logical processor encounters another nested exception while attempting to call the double-fault handler; and that exception does not cause a VM exit due to the exception bitmap; then a VM exit occurs due to triple fault (see Section 22.3).

## VM ENTRIES

- If event delivery injects a double-fault exception and encounters a nested exception that does not cause a VM exit due to the exception bitmap, then a VM exit occurs due to triple fault (see Section 22.3).
- If the “virtualize APIC accesses” VM-execution control is 1 and event delivery generates an access to the APIC-access page, that access may cause an APIC-access VM exit (see Section 22.2) or, if the access is a VTPR access, be treated as specified in Section 22.5.3.<sup>1</sup>

If the event-delivery process does cause a VM exit, the processor state before the VM exit is determined just as it would be had the injected event occurred during normal execution in VMX non-root operation. If the injected event directly accesses a task gate that cause a VM exit or if the first nested exception encountered causes a VM exit, information about the injected event is saved in the IDT-vectoring information field (see Section 24.2.3).

### 23.5.1.3 Event Injection for VM Entries to Real-Address Mode

If VM entry is loading CRO.PE with 0, any injected vectored event is delivered as would normally be done in real-address mode.<sup>2</sup> Specifically, VM entry uses the vector provided in the VM-entry interruption-information field to select a 4-byte entry from an interrupt-vector table at the linear address in IDTR.base. Further details are provided in Section 15.1.4 in Volume 3A of the *IA-32 Intel® Architecture Software Developer’s Manual*.

Because bit 11 (deliver error code) in the VM-entry interruption-information field must be 0 if CRO.PE will be 0 after VM entry (see Section 23.2.1.3), vectored events injected with CRO.PE = 0 do not push an error code on the stack. This is consistent with event delivery in real-address mode.

If event delivery encounters a fault (due to a violation of IDTR.limit or of SS.limit), the fault is treated as if it had occurred during event delivery in VMX non-root operation. Such a fault may lead to a VM exit as discussed in Section 23.5.1.2.

### 23.5.2 Injection of Pending MTF VM Exits

If the interruption type in the VM-entry interruption-information field is 7 (other event) and the vector field is 0, VM entry causes an MTF VM exit to be pending on the instruction boundary following VM entry. This is the case even if the “monitor trap flag” VM-execution control is 0. See Section 22.7.2 for the treatment of pending MTF VM exits.

- 
1. “Virtualize APIC accesses” is a secondary processor-based VM-execution control. If bit 31 of the primary processor-based VM-execution controls is 0, VM entry functions as if the “virtualize APIC accesses” VM-execution control were 0. See Section 21.6.2.
  2. If the capability MSR IA32\_VMX\_CRO\_FIXED0 reports that CRO.PE must be 1 in VMX operation, VM entry must be loading CRO.PE with 1 unless the “unrestricted guest” VM-execution control and bit 31 of the primary processor-based VM-execution controls are both 1.

## 23.6 SPECIAL FEATURES OF VM ENTRY

This section details a variety of features of VM entry. It uses the following terminology: a VM entry is **vectoring** if the valid bit (bit 31) of the VM-entry interruption information field is 1 and the interruption type in the field is 0 (external interrupt), 2 (non-maskable interrupt); 3 (hardware exception), 4 (software interrupt), 5 (privileged software exception), or 6 (software exception).

### 23.6.1 Interruptibility State

The interruptibility-state field in the guest-state area (see Table 21-3) contains bits that control blocking by STI, blocking by MOV SS, and blocking by NMI. This field impacts event blocking after VM entry as follows:

- If the VM entry is vectoring, there is no blocking by STI or by MOV SS following the VM entry, regardless of the contents of the interruptibility-state field.
- If the VM entry is not vectoring, the following apply:
  - Events are blocked by STI if and only if bit 0 in the interruptibility-state field is 1. This blocking is cleared after the guest executes one instruction or incurs an exception (including a debug exception made pending by VM entry; see Section 23.6.3).
  - Events are blocked by MOV SS if and only if bit 1 in the interruptibility-state field is 1. This may affect the treatment of pending debug exceptions; see Section 23.6.3. This blocking is cleared after the guest executes one instruction or incurs an exception (including a debug exception made pending by VM entry).
- The blocking of non-maskable interrupts (NMIs) is determined as follows:
  - If the “virtual NMIs” VM-execution control is 0, NMIs are blocked if and only if bit 3 (blocking by NMI) in the interruptibility-state field is 1. If the “NMI exiting” VM-execution control is 0, execution of the IRET instruction removes this blocking (even if the instruction generates a fault). If the “NMI exiting” control is 1, IRET does not affect this blocking.
  - The following items describe the use of bit 3 (blocking by NMI) in the interruptibility-state field if the “virtual NMIs” VM-execution control is 1:
    - The bit’s value does not affect the blocking of NMIs after VM entry. NMIs are not blocked in VMX non-root operation (except for ordinary blocking for other reasons, such as by the MOV SS instruction, the wait-for-SIPI state, etc.)
    - The bit’s value determines whether there is virtual-NMI blocking after VM entry. If the bit is 1, virtual-NMI blocking is in effect after VM entry. If the bit is 0, there is no virtual-NMI blocking after VM entry unless the VM entry is injecting an NMI (see Section 23.5.1.1). Execution of IRET removes virtual-NMI blocking (even if the instruction generates a fault).

## VM ENTRIES

If the “NMI exiting” VM-execution control is 0, the “virtual NMIs” control must be 0; see Section 23.2.1.1.

- Blocking of system-management interrupts (SMIs) is determined as follows:
  - If the VM entry was not executed in system-management mode (SMM), SMI blocking is unchanged by VM entry.
  - If the VM entry was executed in SMM, SMIs are blocked after VM entry if and only if the bit 2 in the interruptibility-state field is 1.

### 23.6.2 Activity State

The activity-state field in the guest-state area controls whether, after VM entry, the logical processor is active or in one of the inactive states identified in Section 21.4.2. The use of this field is determined as follows:

- If the VM entry is vectoring, the logical processor is in the active state after VM entry. While the consistency checks described in Section 23.3.1.5 on the activity-state field do apply in this case, the contents of the activity-state field do not determine the activity state after VM entry.
- If the VM entry is not vectoring, the logical processor ends VM entry in the activity state specified in the guest-state area. If VM entry ends with the logical processor in an inactive activity state, the VM entry generates any special bus cycle that is normally generated when that activity state is entered from the active state. If VM entry would end with the logical processor in the shutdown state and the logical processor is in SMX operation,<sup>1</sup> an Intel® TXT shutdown condition occurs. The error code used is 0000H, indicating “legacy shutdown.” See *Intel® Trusted Execution Technology Preliminary Architecture Specification*.
- Some activity states unconditionally block certain events. The following blocking is in effect after any VM entry that puts the processor in the indicated state:
  - The active state blocks start-up IPIs (SIPIs). SIPIs that arrive while a logical processor is in the active state and in VMX non-root operation are discarded and do not cause VM exits.
  - The HLT state blocks start-up IPIs (SIPIs). SIPIs that arrive while a logical processor is in the HLT state and in VMX non-root operation are discarded and do not cause VM exits.
  - The shutdown state blocks external interrupts and SIPIs. External interrupts that arrive while a logical processor is in the shutdown state and in VMX non-root operation do not cause VM exits even if the “external-interrupt exiting” VM-execution control is 1. SIPIs that arrive while a logical processor is in the

---

1. A logical processor is in SMX operation if GETSEC[SEXIT] has not been executed since the last execution of GETSEC[SENTER]. See Chapter 6, “Safer Mode Extensions Reference,” in *Intel® 64 and IA-32 Architectures Software Developer’s Manual, Volume 2B*.

shutdown state and in VMX non-root operation are discarded and do not cause VM exits.

- The wait-for-SIPI state blocks external interrupts, non-maskable interrupts (NMIs), INIT signals, and system-management interrupts (SMIs). Such events do not cause VM exits if they arrive while a logical processor is in the wait-for-SIPI state and in VMX non-root operation do not cause VM exits regardless of the settings of the pin-based VM-execution controls.

### 23.6.3 Delivery of Pending Debug Exceptions after VM Entry

The pending debug exceptions field in the guest-state area indicates whether there are debug exceptions that have not yet been delivered (see Section 21.4.2). This section describes how these are treated on VM entry.

There are no pending debug exceptions after VM entry if any of the following are true:

- The VM entry is vectoring with one of the following interruption types: external interrupt, non-maskable interrupt (NMI), hardware exception, or privileged software exception.
- The interruptibility-state field does not indicate blocking by MOV SS and the VM entry is vectoring with either of the following interruption type: software interrupt or software exception.
- The VM entry is not vectoring and the activity-state field indicates either shutdown or wait-for-SIPI.

If none of the above hold, the pending debug exceptions field specifies the debug exceptions that are pending for the guest. There are **valid pending debug exceptions** if either the BS bit (bit 14) or the enable-breakpoint bit (bit 12) is 1. If there are valid pending debug exceptions, they are handled as follows:

- If the VM entry is not vectoring, the pending debug exceptions are treated as they would had they been encountered normally in guest execution:
  - If the logical processor is not blocking such exceptions (the interruptibility-state field indicates no blocking by MOV SS), a debug exception is delivered after VM entry (see below).
  - If the logical processor is blocking such exceptions (due to blocking by MOV SS), the pending debug exceptions are held pending or lost as would normally be the case.
- If the VM entry is vectoring (with interruption type software interrupt or software exception and with blocking by MOV SS), the following items apply:
  - For injection of a software interrupt or of a software exception with vector 3 (#BP) or vector 4 (#OF), the pending debug exceptions are treated as they would had they been encountered normally in guest execution if the corresponding instruction (INT3 or INTO) were executed after a MOV SS that encountered a debug trap.

## VM ENTRIES

- For injection of a software exception with a vector other than 3 and 4, the pending debug exceptions may be lost or they may be delivered after injection (see below).

If there are no valid pending debug exceptions (as defined above), no pending debug exceptions are delivered after VM entry.

If a pending debug exception is delivered after VM entry, it has the priority of “traps on the previous instruction” (see Section 6.9 in the *Intel® 64 and IA-32 Architectures Software Developer’s Manual, Volume 3A*). Thus, INIT signals and system-management interrupts (SMIs) take priority of such an exception, as do VM exits induced by the TPR shadow (see Section 23.6.7) and pending MTF VM exits (see Section 23.6.8). The exception takes priority over any pending non-maskable interrupt (NMI) or external interrupt and also over VM exits due to the 1-settings of the “interrupt-window exiting” and “NMI-window exiting” VM-execution controls.

A pending debug exception delivered after VM entry causes a VM exit if the bit 1 (#DB) is 1 in the exception bitmap. If it does not cause a VM exit, it updates DR6 normally.

### 23.6.4 VMX-Preemption Timer

If the “activate VMX-preemption timer” VM-execution control is 1, VM entry starts the VMX-preemption timer with the unsigned value in the VMX-preemption timer-value field.

It is possible for the VMX-preemption timer to expire during VM entry (e.g., if the value in the VMX-preemption timer-value field is zero). If this happens (and if the VM entry was not to the wait-for-SIPI state), a VM exit occurs with its normal priority after any event injection and before execution of any instruction following VM entry. For example, any pending debug exceptions established by VM entry (see Section 23.6.3) take priority over a timer-induced VM exit. (The timer-induced VM exit will occur after delivery of the debug exception, unless that exception or its delivery causes a different VM exit.)

See Section 22.7.1 for details of the operation of the VMX-preemption timer in VMX non-root operation, including the blocking and priority of the VM exits that it causes.

### 23.6.5 Interrupt-Window Exiting

The “interrupt-window exiting” VM-execution control may cause a VM exit to occur immediately after VM entry (see Section 22.3 for details).

The following items detail the treatment of these VM exits:

- These VM exits follow event injection if such injection is specified for VM entry.
- Non-maskable interrupts (NMIs) and higher priority events take priority over VM exits caused by this control. VM exits caused by this control take priority over external interrupts and lower priority events.

- VM exits caused by this control wake the logical processor if it just entered the HLT state because of a VM entry (see Section 23.6.2). They do not occur if the logical processor just entered the shutdown state or the wait-for-SIPI state.

### 23.6.6 NMI-Window Exiting

The “NMI-window exiting” VM-execution control may cause a VM exit to occur immediately after VM entry (see Section 22.3 for details).

The following items detail the treatment of these VM exits:

- These VM exits follow event injection if such injection is specified for VM entry.
- Debug-trap exceptions (see Section 23.6.3) and higher priority events take priority over VM exits caused by this control. VM exits caused by this control take priority over non-maskable interrupts (NMIs) and lower priority events.
- VM exits caused by this control wake the logical processor if it just entered either the HLT state or the shutdown state because of a VM entry (see Section 23.6.2). They do not occur if the logical processor just entered the wait-for-SIPI state.

### 23.6.7 VM Exits Induced by the TPR Shadow

If the “use TPR shadow” and “virtualize APIC accesses” VM-execution controls are both 1, a VM exit occurs immediately after VM entry if the value of bits 3:0 of the TPR threshold VM-execution control field is greater than the value of bits 7:4 in byte 80H on the virtual-APIC page (see Section 21.6.8).<sup>1</sup>

The following items detail the treatment of these VM exits:

- The VM exits are not blocked if RFLAGS.IF = 0 or by the setting of bits in the interruptibility-state field in guest-state area.
- The VM exits follow event injection if such injection is specified for VM entry.
- VM exits caused by this control take priority over system-management interrupts (SMIs), INIT signals, and lower priority events. They thus have priority over the VM exits described in Section 23.6.5, Section 23.6.6, and Section 23.6.8, as well as any interrupts or debug exceptions that may be pending at the time of VM entry.
- These VM exits wake the logical processor if it just entered the HLT state as part of a VM entry (see Section 23.6.2). They do not occur if the logical processor just entered the shutdown state or the wait-for-SIPI state.

If such a VM exit is suppressed because the processor just entered the shutdown state, it occurs after the delivery of any event that cause the logical

---

1. “Virtualize APIC accesses” is a secondary processor-based VM-execution control. If bit 31 of the primary processor-based VM-execution controls is 0, VM entry functions as if the “virtualize APIC accesses” VM-execution control were 0. See Section 21.6.2.

## VM ENTRIES

processor to leave the shutdown state while remaining in VMX non-root operation (e.g., due to an NMI that occurs while the “NMI-exiting” VM-execution control is 0).

- The basic exit reason is “TPR below threshold.”

### 23.6.8 Pending MTF VM Exits

As noted in Section 23.5.2, VM entry may cause an MTF VM exit to be pending immediately after VM entry. The following items detail the treatment of these VM exits:

- System-management interrupts (SMIs), INIT signals, and higher priority events take priority over these VM exits. These VM exits take priority over debug-trap exceptions and lower priority events.
- These VM exits wake the logical processor if it just entered the HLT state because of a VM entry (see Section 23.6.2). They do not occur if the logical processor just entered the shutdown state or the wait-for-SIPI state.

### 23.6.9 VM Entries and Advanced Debugging Features

VM entries are not logged with last-branch records, do not produce branch-trace messages, and do not update the branch-trace store.

## 23.7 VM-ENTRY FAILURES DURING OR AFTER LOADING GUEST STATE

VM-entry failures due to the checks identified in Section 23.3.1 and failures during the MSR loading identified in Section 23.4 are treated differently from those that occur earlier in VM entry. In these cases, the following steps take place:

1. Information about the VM-entry failure is recorded in the VM-exit information fields:
  - Exit reason.
    - Bits 15:0 of this field contain the basic exit reason. It is loaded with a number indicating the general cause of the VM-entry failure. The following numbers are used:
      33. VM-entry failure due to invalid guest state. A VM entry failed one of the checks identified in Section 23.3.1.
      34. VM-entry failure due to MSR loading. A VM entry failed in an attempt to load MSRs (see Section 23.4).
      41. VM-entry failure due to machine check. A machine check occurred during VM entry (see Section 23.8).

- Bit 31 is set to 1 to indicate a VM-entry failure.
- The remainder of the field (bits 30:16) is cleared.
- Exit qualification. This field is set based on the exit reason.
  - VM-entry failure due to invalid guest state. In most cases, the exit qualification is cleared to 0. The following non-zero values are used in the cases indicated:
    1. Not used.
    2. Failure was due to a problem loading the PDPTEs (see Section 23.3.1.6).
    3. Failure was due to an attempt to inject a non-maskable interrupt (NMI) into a guest that is blocking events through the STI blocking bit in the interruptibility-state field. Such failures are implementation-specific (see Section 23.3.1.5).
    4. Failure was due to an invalid VMCS link pointer (see Section 23.3.1.5).

VM-entry checks on guest-state fields may be performed in any order. Thus, an indication by exit qualification of one cause does not imply that there are not also other errors. Different processors may give different exit qualifications for the same VMCS.

- VM-entry failure due to MSR loading. The exit qualification is loaded to indicate which entry in the VM-entry MSR-load area caused the problem (1 for the first entry, 2 for the second, etc.).
- All other VM-exit information fields are unmodified.
- 2. Processor state is loaded as would be done on a VM exit (see Section 24.5). If this results in [CR4.PAE & CR0.PG & ~IA32\_EFER.LMA] = 1, page-directory-pointer-table entries (PDPTEs) may be checked and loaded (see Section 24.5.4).
- 3. The state of blocking by NMI is what it was before VM entry.
- 4. MSRs are loaded as specified in the VM-exit MSR-load area (see Section 24.6).

Although this process resembles that of a VM exit, many steps taken during a VM exit do not occur for these VM-entry failures:

- Most VM-exit information fields are not updated (see step 1 above).
- The valid bit in the VM-entry interruption-information field is not cleared.
- The guest-state area is not modified.
- No MSRs are saved into the VM-exit MSR-store area.

## 23.8 MACHINE CHECKS DURING VM ENTRY

If a machine check occurs during a VM entry, one of the following occurs:

## VM ENTRIES

- The machine check is handled normally:
  - If CR4.MCE = 1, a machine-check exception (#MC) is delivered through the IDT.
  - If CR4.MCE = 0, operation of the logical processor depends on whether the logical processor is in SMX operation:<sup>1</sup>
    - If the logical processor is in SMX operation, an Intel® TXT shutdown condition occurs. The error code used is 000CH, indicating “unrecoverable machine check condition.” See *Intel® Trusted Execution Technology Preliminary Architecture Specification*.
    - If the logical processor is outside SMX operation, it goes to the shutdown state.
- A VM-entry failure occurs as described in Section 23.7. The basic exit reason is 41, for “VM-entry failure due to machine check.”

The first option is not used if the machine check occurs after any guest state has been loaded.

---

1. A logical processor is in SMX operation if GETSEC[SEXIT] has not been executed since the last execution of GETSEC[SENTER]. A logical processor is outside SMX operation if GETSEC[SENTER] has not been executed or if GETSEC[SEXIT] was executed after the last execution of GETSEC[SENTER]. See Chapter 6, “Safer Mode Extensions Reference,” in *Intel® 64 and IA-32 Architectures Software Developer’s Manual, Volume 2B*.

## CHAPTER 24

### VM EXITS

---

VM exits occur in response to certain instructions and events in VMX non-root operation. Section 22.1 through Section 22.3 detail the causes of VM exits. VM exits perform the following operation:

1. Information about the cause of the VM exit is recorded in the VM-exit information fields and VM-entry control fields are modified as described in Section 24.2.
2. Processor state is saved in the guest-state area (Section 24.3).
3. MSRs may be saved in the VM-exit MSR-store area (Section 24.4).
4. The following may be performed in parallel and in any order (Section 24.5):
  - Processor state is loaded based in part on the host-state area and some VM-exit controls. This step is not performed for SMM VM exits that activate the dual-monitor treatment of SMIs and SMM. See Section 26.15.6 for information on how processor state is loaded by such VM exits.
  - Address-range monitoring is cleared.
5. MSRs may be loaded from the VM-exit MSR-load area (Section 24.6). This step is not performed for SMM VM exits that activate the dual-monitor treatment of SMIs and SMM.

VM exits are not logged with last-branch records, do not produce branch-trace messages, and do not update the branch-trace store.

Section 24.1 clarifies the nature of the architectural state before a VM exit begins. The steps described above are detailed in Section 24.2 through Section 24.6.

Section 26.15 describes the dual-monitor treatment of system-management interrupts (SMIs) and system-management mode (SMM). Under this treatment, ordinary transitions to SMM are replaced by VM exits to a separate SMM monitor. Called **SMM VM exits**, these are caused by the arrival of an SMI or the execution of VMCALL in VMX root operation. SMM VM exits differ from other VM exits in ways that are detailed in Section 26.15.2.

## 24.1 ARCHITECTURAL STATE BEFORE A VM EXIT

This section describes the architectural state that exists before a VM exit, especially for VM exits caused by events that would normally be delivered through the IDT.

Note the following:

- An exception causes a VM exit **directly** if the bit corresponding to that exception is set in the exception bitmap. A non-maskable interrupt (NMI) causes a VM exit directly if the “NMI exiting” VM-execution control is 1. An external interrupt

## VM EXITS

causes a VM exit directly if the “external-interrupt exiting” VM-execution control is 1. A start-up IPI (SIPI) that arrives while a logical processor is in the wait-for-SIPI activity state causes a VM exit directly. INIT signals that arrive while the processor is not in the wait-for-SIPI activity state cause VM exits directly.

- An exception, NMI, external interrupt, or software interrupt causes a VM exit **indirectly** if it does not do so directly but delivery of the event causes a nested exception, double fault, task switch, APIC access (see Section 22.2), EPT violation, or EPT misconfiguration that causes a VM exit.
- An event **results** in a VM exit if it causes a VM exit (directly or indirectly).

The following bullets detail when architectural state is and is not updated in response to VM exits:

- If an event causes a VM exit directly, it does not update architectural state as it would have if it had not caused the VM exit:
  - A debug exception does not update DR6, DR7.GD, or IA32\_DEBUGCTL.LBR. (Information about the nature of the debug exception is saved in the exit qualification field.)
  - A page fault does not update CR2. (The linear address causing the page fault is saved in the exit-qualification field.)
  - An NMI causes subsequent NMIs to be blocked, but only after the VM exit completes.
  - An external interrupt does not acknowledge the interrupt controller and the interrupt remains pending, unless the “acknowledge interrupt on exit” VM-exit control is 1. In such a case, the interrupt controller is acknowledged and the interrupt is no longer pending.
  - The flags L0 – L3 in DR7 (bit 0, bit 2, bit 4, and bit 6) are not cleared when a task switch causes a VM exit.
  - If a task switch causes a VM exit, none of the following are modified by the task switch: old task-state segment (TSS); new TSS; old TSS descriptor; new TSS descriptor; RFLAGS.NT<sup>1</sup>; or the TR register.
  - No last-exception record is made if the event that would do so directly causes a VM exit.
  - If a machine-check exception causes a VM exit directly, this does not prevent machine-check MSRs from being updated. These are updated by the machine check itself and not the resulting machine-check exception.

---

1. This chapter uses the notation RAX, RIP, RSP, RFLAGS, etc. for processor registers because most processors that support VMX operation also support Intel 64 architecture. For processors that do not support Intel 64 architecture, this notation refers to the 32-bit forms of those registers (EAX, EIP, ESP, EFLAGS, etc.). In a few places, notation such as EAX is used to refer specifically to lower 32 bits of the indicated register.

- If the logical processor is in an inactive state (see Section 21.4.2) and not executing instructions, some events may be blocked but others may return the logical processor to the active state. Unblocked events may cause VM exits.<sup>1</sup> If an unblocked event causes a VM exit directly, a return to the active state occurs only after the VM exit completes.<sup>2</sup> The VM exit generates any special bus cycle that is normally generated when the active state is entered from that activity state.

MTF VM exits (see Section 22.7.2 and Section 23.6.8) are not blocked in the HLT activity state. If an MTF VM exit occurs in the HLT activity state, the logical processor returns to the active state only after the VM exit completes. MTF VM exits are blocked the shutdown state and the wait-for-SIPI state.

- If an event causes a VM exit indirectly, the event does update architectural state:
  - A debug exception updates DR6, DR7, and the IA32\_DEBUGCTL MSR. No debug exceptions are considered pending.
  - A page fault updates CR2.
  - An NMI causes subsequent NMIs to be blocked before the VM exit commences.
  - An external interrupt acknowledges the interrupt controller and the interrupt is no longer pending.
  - If the logical processor had been in an inactive state, it enters the active state and, before the VM exit commences, generates any special bus cycle that is normally generated when the active state is entered from that activity state.
  - There is no blocking by STI or by MOV SS when the VM exit commences.
  - Processor state that is normally updated as part of delivery through the IDT (CS, RIP, SS, RSP, RFLAGS) is not modified. However, the incomplete delivery of the event may write to the stack.
  - The treatment of last-exception records is implementation dependent:
    - Some processors make a last-exception record when beginning the delivery of an event through the IDT (before it can encounter a nested exception). Such processors perform this update even if the event encounters a nested exception that causes a VM exit (including the case where nested exceptions lead to a triple fault).
    - Other processors delay making a last-exception record until event delivery has reached some event handler successfully (perhaps after one or more nested exceptions). Such processors do not update the last-

- 
1. If a VM exit takes the processor from an inactive state resulting from execution of a specific instruction (HLT or MWAIT), the value saved for RIP by that VM exit will reference the following instruction.
  2. An exception is made if the logical processor had been inactive due to execution of MWAIT; in this case, it is considered to have become active before the VM exit.

## VM EXITS

exception record if a VM exit or triple fault occurs before an event handler is reached.

- If the “virtual NMIs” VM-execution control is 1, VM entry injects an NMI, and delivery of the NMI causes a nested exception, double fault, task switch, or APIC access that causes a VM exit, virtual-NMI blocking is in effect before the VM exit commences.
- If a VM exit results from a fault, EPT violation, or EPT misconfiguration encountered during execution of IRET and the “NMI exiting” VM-execution control is 0, any blocking by NMI is cleared before the VM exit commences. However, the previous state of blocking by NMI may be recorded in the VM-exit interruption-information field; see Section 24.2.2.
- If a VM exit results from a fault, EPT violation, or EPT misconfiguration encountered during execution of IRET and the “virtual NMIs” VM-execution control is 1, virtual-NMI blocking is cleared before the VM exit commences. However, the previous state of virtual-NMI blocking may be recorded in the VM-exit interruption-information field; see Section 24.2.2.
- Suppose that a VM exit is caused directly by an x87 FPU Floating-Point Error (#MF) or by any of the following events if the event was unblocked due to (and given priority over) an x87 FPU Floating-Point Error: an INIT signal, an external interrupt, an NMI, an SMI; or a machine-check exception. In these cases, there is no blocking by STI or by MOV SS when the VM exit commences.
- Normally, a last-branch record may be made when an event is delivered through the IDT. However, if such an event results in a VM exit before delivery is complete, no last-branch record is made.
- If machine-check exception results in a VM exit, processor state is suspect and may result in suspect state being saved to the guest-state area. A VM monitor should consult the RIPV and EIPV bits in the IA32\_MCG\_STATUS MSR before resuming a guest that caused a VM exit resulting from a machine-check exception.
- If a VM exit results from a fault, APIC access (see Section 22.2), EPT violation, or EPT misconfiguration encountered while executing an instruction, data breakpoints due to that instruction may have been recognized and information about them may be saved in the pending debug exceptions field (see Section 24.3.4).
- The following VM exits are considered to happen after an instruction is executed:
  - VM exits resulting from debug traps (single-step, I/O breakpoints, and data breakpoints).
  - VM exits resulting from debug exceptions whose recognition was delayed by blocking by MOV SS.
  - VM exits resulting from some machine-check exceptions.
  - Trap-like VM exits due to execution of MOV to CR8 when the “CR8-load exiting” VM-execution control is 0 and the “use TPR shadow” VM-execution

control is 1. (Such VM exits can occur only from 64-bit mode and thus only on processors that support Intel 64 architecture.)

- Trap-like VM exits due to execution of WRMSR when the “use MSR bitmaps” VM-execution control is 1, the value of ECX is 808H, bit 808H in write bitmap for low MSRs is 0, and the “virtualize x2APIC mode” VM-execution control is 1. See Section 22.1.3.
- VM exits caused by TPR-shadow updates (see Section 22.5.3.3) that result from APIC accesses as part of instruction execution.

For these VM exits, the instruction’s modifications to architectural state complete before the VM exit occurs. Such modifications include those to the logical processor’s interruptibility state (see Table 21-3). If there had been blocking by MOV SS, POP SS, or STI before the instruction executed, such blocking is no longer in effect.

## 24.2 RECORDING VM-EXIT INFORMATION AND UPDATING VM-ENTRY CONTROL FIELDS

VM exits begin by recording information about the nature of and reason for the VM exit in the VM-exit information fields. Section 24.2.1 to Section 24.2.4 detail the use of these fields.

In addition to updating the VM-exit information fields, the valid bit (bit 31) is cleared in the VM-entry interruption-information field. If bit 5 of the IA32\_VMX\_MISC MSR (index 485H) is read as 1 (see Appendix G.6), the value of IA32\_EFER.LMA is stored into the “IA-32e mode guest” VM-entry control.<sup>1</sup>

### 24.2.1 Basic VM-Exit Information

Section 21.9.1 defines the basic VM-exit information fields. The following items detail their use.

- **Exit reason.**
  - Bits 15:0 of this field contain the basic exit reason. It is loaded with a number indicating the general cause of the VM exit. Appendix I lists the numbers used and their meaning.
  - The remainder of the field (bits 31:16) is cleared to 0 (certain SMM VM exits may set some of these bits; see Section 26.15.2.3).<sup>2</sup>

---

1. Bit 5 of the IA32\_VMX\_MISC MSR is read as 1 on any logical processor that supports the 1-setting of the “unrestricted guest” VM-execution control.

2. Bit 13 of this field is set on certain VM-entry failures; see Section 23.7.

## VM EXITS

- **Exit qualification.** This field is saved for VM exits due to the following causes: debug exceptions; page-fault exceptions; start-up IPIs (SIPIs); system-management interrupts (SMIs) that arrive immediately after the retirement of I/O instructions; task switches; INVEPT; INVLPG; INVPID; LGDT; LIDT; LLDT; LTR; SGDT; SIDT; SLDT; STR; VMCLEAR; VMPLRD; VMPLRST; VMREAD; VMWRITE; VMXON; control-register accesses; MOV DR; I/O instructions; MWAIT; accesses to the APIC-access page (see Section 22.2); and EPT violations. For all other VM exits, this field is cleared. The following items provide details:
  - For a debug exception, the exit qualification contains information about the debug exception. The information has the format given in Table 24-1.

Table 24-1. Exit Qualification for Debug Exceptions

| Bit Position(s) | Contents                                                                                                                                                                                                                 |
|-----------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 3:0             | B3 – B0. When set, each of these bits indicates that the corresponding breakpoint condition was met. Any of these bits may be set even if its corresponding enabling bit in DR7 is not set.                              |
| 12:4            | Reserved (cleared to 0).                                                                                                                                                                                                 |
| 13              | BD. When set, this bit indicates that the cause of the debug exception is “debug register access detected.”                                                                                                              |
| 14              | BS. When set, this bit indicates that the cause of the debug exception is either the execution of a single instruction (if RFLAGS.TF = 1 and IA32_DEBUGCTL.BTF = 0) or a taken branch (if RFLAGS.TF = DEBUGCTL.BTF = 1). |
| 63:15           | Reserved (cleared to 0). Bits 63:32 exist only on processors that support Intel 64 architecture.                                                                                                                         |

- For a page-fault exception, the exit qualification contains the linear address that caused the page fault. On processors that support Intel 64 architecture, bits 63:32 are cleared if the logical processor was not in 64-bit mode before the VM exit.
- For a start-up IPI (SIPPI), the exit qualification contains the SIPI vector information in bits 7:0. Bits 63:8 of the exit qualification are cleared to 0.
- For a task switch, the exit qualification contains details about the task switch, encoded as shown in Table 24-2.

Table 24-2. Exit Qualification for Task Switch

| Bit Position(s) | Contents                                                                    |
|-----------------|-----------------------------------------------------------------------------|
| 15:0            | Selector of task-state segment (TSS) to which the guest attempted to switch |

Table 24-2. Exit Qualification for Task Switch (Contd.)

| Bit Position(s) | Contents                                                                                                                     |
|-----------------|------------------------------------------------------------------------------------------------------------------------------|
| 29:16           | Reserved (cleared to 0)                                                                                                      |
| 31:30           | Source of task switch initiation:<br>0: CALL instruction<br>1: IRET instruction<br>2: JMP instruction<br>3: Task gate in IDT |
| 63:32           | Reserved (cleared to 0). These bits exist only on processors that support Intel 64 architecture.                             |

- For INVLPG, the exit qualification contains the linear-address operand of the instruction.
  - On processors that support Intel 64 architecture, bits 63:32 are cleared if the logical processor was not in 64-bit mode before the VM exit.
  - If the INVLPG source operand specifies an unusable segment, the linear address specified in the exit qualification will match the linear address that the INVLPG would have used if no VM exit occurred. This address is not architecturally defined and may be implementation-specific.
- For INVEPT, INVVPID, LGDT, LIDT, LLDT, LTR, SGDT, SIDT, SLDT, STR, VMCLEAR, VMPTRLD, VMPTRST, VMREAD, VMWRITE, and VMXON, the exit qualification receives the value of the instruction's displacement field, which is sign-extended to 64 bits if necessary (32 bits on processors that do not support Intel 64 architecture). If the instruction has no displacement (for example, has a register operand), zero is stored into the exit qualification.

On processors that support Intel 64 architecture, an exception is made for RIP-relative addressing (used only in 64-bit mode). Such addressing causes an instruction to use an address that is the sum of the displacement field and the value of RIP that references the following instruction. In this case, the exit qualification is loaded with the sum of the displacement field and the appropriate RIP value.

In all cases, bits of this field beyond the instruction's address size are undefined. For example, suppose that the address-size field in the VM-exit instruction-information field (see Section 21.9.4 and Section 24.2.4) reports an  $n$ -bit address size. Then bits 63: $n$  (bits 31: $n$  on processors that do not support Intel 64 architecture) of the instruction displacement are undefined.

## VM EXITS

- For a control-register access, the exit qualification contains information about the access and has the format given in Table 24-3.

**Table 24-3. Exit Qualification for Control-Register Accesses**

| Bit Positions | Contents                                                                                                                                                                                                                                                                     |
|---------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 3:0           | Number of control register (0 for CLTS and LMSW). Bit 3 is always 0 on processors that do not support Intel 64 architecture as they do not support CR8.                                                                                                                      |
| 5:4           | Access type:<br>0 = MOV to CR<br>1 = MOV from CR<br>2 = CLTS<br>3 = LMSW                                                                                                                                                                                                     |
| 6             | LMSW operand type:<br>0 = register<br>1 = memory<br><br>For CLTS and MOV CR, cleared to 0                                                                                                                                                                                    |
| 7             | Reserved (cleared to 0)                                                                                                                                                                                                                                                      |
| 11:8          | For MOV CR, the general-purpose register:<br>0 = RAX<br>1 = RCX<br>2 = RDX<br>3 = RBX<br>4 = RSP<br>5 = RBP<br>6 = RSI<br>7 = RDI<br>8-15 represent R8-R15, respectively (used only on processors that support Intel 64 architecture)<br><br>For CLTS and LMSW, cleared to 0 |
| 15:12         | Reserved (cleared to 0)                                                                                                                                                                                                                                                      |
| 31:16         | For LMSW, the LMSW source data<br>For CLTS and MOV CR, cleared to 0                                                                                                                                                                                                          |
| 63:32         | Reserved (cleared to 0). These bits exist only on processors that support Intel 64 architecture.                                                                                                                                                                             |

- For MOV DR, the exit qualification contains information about the instruction and has the format given in Table 24-4.

Table 24-4. Exit Qualification for MOV DR

| Bit Position(s) | Contents                                                                                                                                             |
|-----------------|------------------------------------------------------------------------------------------------------------------------------------------------------|
| 2:0             | Number of debug register                                                                                                                             |
| 3               | Reserved (cleared to 0)                                                                                                                              |
| 4               | Direction of access (0 = MOV to DR; 1 = MOV from DR)                                                                                                 |
| 7:5             | Reserved (cleared to 0)                                                                                                                              |
| 11:8            | General-purpose register:<br>0 = RAX<br>1 = RCX<br>2 = RDX<br>3 = RBX<br>4 = RSP<br>5 = RBP<br>6 = RSI<br>7 = RDI<br>8 - 15 = R8 - R15, respectively |
| 63:12           | Reserved (cleared to 0)                                                                                                                              |

- For an I/O instruction, the exit qualification contains information about the instruction and has the format given in Table 24-5.

Table 24-5. Exit Qualification for I/O Instructions

| Bit Position(s) | Contents                                                                               |
|-----------------|----------------------------------------------------------------------------------------|
| 2:0             | Size of access:<br>0 = 1-byte<br>1 = 2-byte<br>3 = 4-byte<br><br>Other values not used |
| 3               | Direction of the attempted access (0 = OUT, 1 = IN)                                    |
| 4               | String instruction (0 = not string; 1 = string)                                        |

## VM EXITS

**Table 24-5. Exit Qualification for I/O Instructions (Contd.)**

| Bit Position(s) | Contents                                                                                         |
|-----------------|--------------------------------------------------------------------------------------------------|
| 5               | REP prefixed (0 = not REP; 1 = REP)                                                              |
| 6               | Operand encoding (0 = DX, 1 = immediate)                                                         |
| 15:7            | Reserved (cleared to 0)                                                                          |
| 31:16           | Port number (as specified in DX or in an immediate operand)                                      |
| 63:32           | Reserved (cleared to 0). These bits exist only on processors that support Intel 64 architecture. |

- For MWAIT, the exit qualification contains a value that indicates whether address-range monitoring hardware was armed. The exit qualification is set either to 0 (if address-range monitoring hardware is not armed) or to 1 (if address-range monitoring hardware is armed).
- For an APIC-access VM exit resulting from a linear access or a guest-physical access to the APIC-access page (see Section 22.2.1 and Section 22.2.2), the exit qualification contains information about the access and has the format given in Table 24-6.<sup>1</sup>

**Table 24-6. Exit Qualification for APIC-Access VM Exits from Linear Accesses and Guest-Physical Accesses**

| Bit Position(s) | Contents                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|-----------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 11:0            | <ul style="list-style-type: none"> <li>▪ If the APIC-access VM exit is due to a linear access, the offset of access within the APIC page.</li> <li>▪ Undefined if the APIC-access VM exit is due a guest-physical access</li> </ul>                                                                                                                                                                                                                                                                                    |
| 15:12           | <p>Access type:</p> <ul style="list-style-type: none"> <li>0 = linear access for a data read during instruction execution</li> <li>1 = linear access for a data write during instruction execution</li> <li>2 = linear access for an instruction fetch</li> <li>3 = linear access (read or write) during event delivery</li> <li>10 = guest-physical access during event delivery</li> <li>15 = guest-physical access for an instruction fetch or during instruction execution</li> </ul> <p>Other values not used</p> |
| 63:16           | Reserved (cleared to 0). Bits 63:32 exist only on processors that support Intel 64 architecture.                                                                                                                                                                                                                                                                                                                                                                                                                       |

Such a VM exit that set bits 15:12 of the exit qualification to 0000b (data read during instruction execution) or 0001b (data write during instruction execution) set bit 12—which distinguishes data read from data write—to that which would have been stored in bit 1—W/R—of the page-fault error code had the access caused a page fault instead of an APIC-access VM exit. This implies the following:

- For an APIC-access VM exit caused by the CLFLUSH instruction, the access type is “data read during instruction execution.”
- For an APIC-access VM exit caused by the ENTER instruction, the access type is “data write during instruction execution.”
- For an APIC-access VM exit caused by the MASKMOVQ instruction or the MASKMOVDQU instruction, the access type is “data write during instruction execution.”
- For an APIC-access VM exit caused by the MONITOR instruction, the access type is “data read during instruction execution.”

Such a VM exit stores 1 for bit 31 for IDT-vectoring information field (see Section 24.2.3) if and only if it sets bits 15:12 of the exit qualification to 0011b (linear access during event delivery) or 1010b (guest-physical access during event delivery).

See Section 22.2.1.3 for further discussion of these instructions and APIC-access VM exits.

For APIC-access VM exits resulting from physical accesses, the APIC-access page (see Section 22.2.3), the exit qualification is undefined.

- For an EPT violation, the exit qualification contains information about the access causing the EPT violation and has the format given in Table 24-5.

**Table 24-7. Exit Qualification for EPT Violations**

| Bit Position(s) | Contents                                                              |
|-----------------|-----------------------------------------------------------------------|
| 0               | Set if the access causing the EPT violation was a data read.          |
| 1               | Set if the access causing the EPT violation was a data write.         |
| 2               | Set if the access causing the EPT violation was an instruction fetch. |

- 
1. The exit qualification is undefined if the access was part of the logging of a branch record or a precise-event-based-sampling (PEBS) record to the DS save area. It is recommended that software configure the paging structures so that no address in the DS save area translates to an address on the APIC-access page.

Table 24-7. Exit Qualification for EPT Violations (Contd.)

| Bit Position(s) | Contents                                                                                                                                                                                                                                                                                                                                                                                    |
|-----------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 3               | The logical-AND of bit 0 in the EPT paging-structures entries used to translate the guest-physical address of the access causing the EPT violation (indicates that the guest-physical address was readable). <sup>1</sup>                                                                                                                                                                   |
| 4               | The logical-AND of bit 1 in the EPT paging-structures entries used to translate the guest-physical address of the access causing the EPT violation (indicates that the guest-physical address was writeable).                                                                                                                                                                               |
| 5               | The logical-AND of bit 2 in the EPT paging-structures entries used to translate the guest-physical address of the access causing the EPT violation (indicates that the guest-physical address was executable).                                                                                                                                                                              |
| 6               | Reserved (cleared to 0).                                                                                                                                                                                                                                                                                                                                                                    |
| 7               | Set if the guest linear-address field is valid.<br>The guest linear-address field is valid for all EPT violations except those resulting from an attempt to load the guest PDPTes as part of the execution of the MOV CR instruction.                                                                                                                                                       |
| 8               | If bit 7 is 1: <ul style="list-style-type: none"> <li>▪ Set if the access causing the EPT violation is to a guest-physical address that is the translation of a linear address.</li> <li>▪ Clear if the access causing the EPT violation is to a paging-structure entry as part of a page walk or the update of an accessed or dirty bit.</li> </ul> Reserved if bit 7 is 0 (cleared to 0). |
| 11:9            | Reserved (cleared to 0).                                                                                                                                                                                                                                                                                                                                                                    |
| 12              | NMI unblocking due to IRET                                                                                                                                                                                                                                                                                                                                                                  |
| 63:13           | Reserved (cleared to 0).                                                                                                                                                                                                                                                                                                                                                                    |

**NOTES:**

1. Bits 5:3 are cleared to 0 if any of EPT paging-structures entries used to translate the guest-physical address of the access causing the EPT violation is not present (see Section 25.2.2).

An EPT violation that occurs during as a result of execution of a read-modify-write operation sets bit 1 (data write). Whether it also sets bit 0 (data read) is implementation-specific and, for a given implementation, may differ for different kinds of read-modify-write operations.

Bit 12 is undefined in any of the following cases:

- If the “NMI exiting” VM-execution control is 1 and the “virtual NMIs” VM-execution control is 0.

- If the VM exit sets the valid bit in the IDT-vectoring information field (see Section 24.2.3).

Otherwise, bit 12 is defined as follows:

- If the “virtual NMIs” VM-execution control is 0, the EPT violation was caused by a memory access as part of execution of the IRET instruction, and blocking by NMI (see Table 21-3) was in effect before execution of IRET, bit 12 is set to 1.
- If the “virtual NMIs” VM-execution control is 1, the EPT violation was caused by a memory access as part of execution of the IRET instruction, and virtual-NMI blocking was in effect before execution of IRET, bit 12 is set to 1.
- For all other relevant VM exits, bit 12 is cleared to 0.
- **Guest-linear address.** For some VM exits, this field receives a linear address that pertains to the VM exit. The field is set for different VM exits as follows:
  - VM exits due to attempts to execute LMSW with a memory operand. In these cases, this field receives the linear address of that operand. Bits 63:32 are cleared if the logical processor was not in 64-bit mode before the VM exit.
  - VM exits due to attempts to execute INS or OUTS for which the relevant segment is usable (if the relevant segment is not usable, the value is undefined). (ES is always the relevant segment for INS; for OUTS, the relevant segment is DS unless overridden by an instruction prefix.) The linear address is the base address of relevant segment plus (E)DI (for INS) or (E)SI (for OUTS). Bits 63:32 are cleared if the logical processor was not in 64-bit mode before the VM exit.
  - VM exits due to EPT violations that set bit 7 of the exit qualification (see Table 24-7; these are all EPT violations except those resulting from an attempt to load the PDPTEs as of execution of the MOV CR instruction). The linear address may translate to the guest-physical address whose access caused the EPT violation. Alternatively, translation of the linear address may reference a paging-structure entry whose access caused the EPT violation. Bits 63:32 are cleared if the logical processor was not in 64-bit mode before the VM exit.
  - For all other VM exits, the field is undefined.
- **Guest-physical address.** For a VM exit due to an EPT violation or an EPT misconfiguration, this field receives the guest-physical address that caused the EPT violation or EPT misconfiguration. For all other VM exits, the field is undefined.

## 24.2.2 Information for VM Exits Due to Vectored Events

Section 21.9.2 defines fields containing information for VM exits due to the following events: exceptions (including those generated by the instructions INT3, INTO,

## VM EXITS

BOUND, and UD2); external interrupts that occur while the “acknowledge interrupt on exit” VM-exit control is 1; and non-maskable interrupts (NMIs). Such VM exits include those that occur on an attempt at a task switch that causes an exception before generating the VM exit due to the task switch that causes the VM exit.

The following items detail the use of these fields:

- **VM-exit interruption information** (format given in Table 21-14). The following items detail how this field is established for VM exits due to these events:
  - For an exception, bits 7:0 receive the exception vector (at most 31). For an NMI, bits 7:0 are set to 2. For an external interrupt, bits 7:0 receive the interrupt number.
  - Bits 10:8 are set to 0 (external interrupt), 2 (non-maskable interrupt), 3 (hardware exception), or 6 (software exception). Hardware exceptions comprise all exceptions except breakpoint exceptions (#BP; generated by INT3) and overflow exceptions (#OF; generated by INTO); these are software exceptions. BOUND-range exceeded exceptions (#BR; generated by BOUND) and invalid opcode exceptions (#UD; generated by UD2) are hardware exceptions.
  - Bit 11 is set to 1 if the VM exit is caused by a hardware exception that would have delivered an error code on the stack. This bit is always 0 if the VM exit occurred while the logical processor was in real-address mode (CRO.PE=0).<sup>1</sup> If bit 11 is set to 1, the error code is placed in the VM-exit interruption error code (see below).
  - Bit 12 is undefined in any of the following cases:
    - If the “NMI exiting” VM-execution control is 1 and the “virtual NMIs” VM-execution control is 0.
    - If the VM exit sets the valid bit in the IDT-vectoring information field (see Section 24.2.3).
    - If the VM exit is due to a double fault (the interruption type is hardware exception and the vector is 8).

Otherwise, bit 12 is defined as follows:

- If the “virtual NMIs” VM-execution control is 0, the VM exit is due to a fault on the IRET instruction (other than a debug exception for an instruction breakpoint), and blocking by NMI (see Table 21-3) was in effect before execution of IRET, bit 12 is set to 1.
- If the “virtual NMIs” VM-execution control is 1, the VM exit is due to a fault on the IRET instruction (other than a debug exception for an

---

1. If the capability MSR IA32\_VMX\_CRO\_FIXED0 reports that CRO.PE must be 1 in VMX operation, a logical processor cannot be in real-address mode unless the “unrestricted guest” VM-execution control and bit 31 of the primary processor-based VM-execution controls are both 1.

instruction breakpoint), and virtual-NMI blocking was in effect before execution of IRET, bit 12 is set to 1.

- For all other relevant VM exits, bit 12 is cleared to 0.<sup>1</sup>
- Bits 30:13 are always set to 0.
- Bit 31 is always set to 1.

For other VM exits (including those due to external interrupts when the “acknowledge interrupt on exit” VM-exit control is 0), the field is marked invalid (by clearing bit 31) and the remainder of the field is undefined.

- VM-exit interruption error code.
  - For VM exits that set both bit 31 (valid) and bit 11 (error code valid) in the VM-exit interruption-information field, this field receives the error code that would have been pushed on the stack had the event causing the VM exit been delivered normally through the IDT. The EXT bit is set in this field exactly when it would be set normally. For exceptions that occur during the delivery of double fault (if the IDT-vectoring information field indicates a double fault), the EXT bit is set to 1, assuming that (1) that the exception would produce an error code normally (if not incident to double-fault delivery) and (2) that the error code uses the EXT bit (not for page faults, which use a different format).
  - For other VM exits, the value of this field is undefined.

### 24.2.3 Information for VM Exits During Event Delivery

Section 21.9.3 defined fields containing information for VM exits that occur while delivering an event through the IDT and as a result of any of the following cases:<sup>2</sup>

- A fault occurs during event delivery and causes a VM exit (because the bit associated with the fault is set to 1 in the exception bitmap).
- A task switch is invoked through a task gate in the IDT. The VM exit occurs due to the task switch only after the initial checks of the task switch pass (see Section 22.6.2).
- Event delivery causes an APIC-access VM exit (see Section 22.2).
- An EPT violation or EPT misconfiguration that occurs during event delivery.

These fields are used for VM exits that occur during delivery of events injected as part of VM entry (see Section 23.5.1.2).

- 
1. The conditions imply that, if the “NMI exiting” VM-execution control is 0 or the “virtual NMIs” VM-execution control is 1, bit 12 is always cleared to 0 by VM exits due to debug exceptions.
  2. This includes the case in which a VM exit occurs while delivering a software interrupt (INT *n*) through the 16-bit IVT (interrupt vector table) that is used in virtual-8086 mode with virtual-machine extensions (if RFLAGS.VM = CR4.VME = 1).

## VM EXITS

A VM exit is not considered to occur during event delivery in any of the following circumstances:

- The original event causes the VM exit directly (for example, because the original event is a non-maskable interrupt (NMI) and the “NMI exiting” VM-execution control is 1).
- The original event results in a double-fault exception that causes the VM exit directly.
- The VM exit occurred as a result of fetching the first instruction of the handler invoked by the event delivery.
- The VM exit is caused by a triple fault.

The following items detail the use of these fields:

- IDT-vectoring information (format given in Table 21-15). The following items detail how this field is established for VM exits that occur during event delivery:
  - If the VM exit occurred during delivery of an exception, bits 7:0 receive the exception vector (at most 31). If the VM exit occurred during delivery of an NMI, bits 7:0 are set to 2. If the VM exit occurred during delivery of an external interrupt, bits 7:0 receive the interrupt number.
  - Bits 10:8 are set to indicate the type of event that was being delivered when the VM exit occurred: 0 (external interrupt), 2 (non-maskable interrupt), 3 (hardware exception), 4 (software interrupt), 5 (privileged software interrupt), or 6 (software exception).

Hardware exceptions comprise all exceptions except breakpoint exceptions (#BP; generated by INT3) and overflow exceptions (#OF; generated by INTO); these are software exceptions. BOUND-range exceeded exceptions (#BR; generated by BOUND) and invalid opcode exceptions (#UD) generated by UD2 are hardware exceptions.

Bits 10:8 may indicate privileged software interrupt if such an event was injected as part of VM entry.

- Bit 11 is set to 1 if the VM exit occurred during delivery of a hardware exception that would have delivered an error code on the stack. This bit is always 0 if the VM exit occurred while the logical processor was in real-address mode (CRO.PE=0).<sup>1</sup> If bit 11 is set to 1, the error code is placed in the IDT-vectoring error code (see below).
- Bit 12 is undefined.
- Bits 30:13 are always set to 0.
- Bit 31 is always set to 1.

---

1. If the capability MSR IA32\_VMX\_CRO\_FIXED0 reports that CRO.PE must be 1 in VMX operation, a logical processor cannot be in real-address mode unless the “unrestricted guest” VM-execution control and bit 31 of the primary processor-based VM-execution controls are both 1.

For other VM exits, the field is marked invalid (by clearing bit 31) and the remainder of the field is undefined.

- IDT-vectoring error code.
  - For VM exits that set both bit 31 (valid) and bit 11 (error code valid) in the IDT-vectoring information field, this field receives the error code that would have been pushed on the stack by the event that was being delivered through the IDT at the time of the VM exit. The EXT bit is set in this field when it would be set normally.
  - For other VM exits, the value of this field is undefined.

#### 24.2.4 Information for VM Exits Due to Instruction Execution

Section 21.9.4 defined fields containing information for VM exits that occur due to instruction execution. (The VM-exit instruction length is also used for VM exits that occur during the delivery of a software interrupt or software exception.) The following items detail their use.

- **VM-exit instruction length.** This field is used in the following cases:
  - For fault-like VM exits due to attempts to execute one of the following instructions that cause VM exits unconditionally (see Section 22.1.2) or based on the settings of VM-execution controls (see Section 22.1.3): CLTS, CPUID, GETSEC, HLT, IN, INS, INVD, INVEPT, INVLPG, INVVPID, LGDT, LIDT, LLDT, LMSW, LTR, MONITOR, MOV CR, MOV DR, MWAIT, OUT, OUTS, PAUSE, RDMSR, RDPMC, RDTSC, RDTSCP, RSM, SGDT, SIDT, SLDT, STR, VMCALL, VMCLEAR, VMLAUNCH, VMPTRLD, VMPTRST, VMREAD, VMRESUME, VMWRITE, VMXOFF, VMXON, WBINVD, WRMSR, and XSETBV.<sup>1</sup>
  - For VM exits due to software exceptions (those generated by executions of INT3 or INTO).
  - For VM exits due to faults encountered during delivery of a software interrupt, privileged software exception, or software exception.
  - For VM exits due to attempts to effect a task switch via instruction execution. These are VM exits that produce an exit reason indicating task switch and either of the following:
    - An exit qualification indicating execution of CALL, IRET, or JMP instruction.
    - An exit qualification indicating a task gate in the IDT and an IDT-vectoring information field indicating that the task gate was encountered during

---

1. This item applies only to fault-like VM exits. It does not apply to trap-like VM exits following executions of the MOV to CR8 instruction when the “use TPR shadow” VM-execution control is 1 or to those following executions of the WRMSR instruction when the “virtualize x2APIC mode” VM-execution control is 1.

## VM EXITS

delivery of a software interrupt, privileged software exception, or software exception.

- For APIC-access VM exits resulting from linear accesses (see Section 22.2.1) and encountered during delivery of a software interrupt, privileged software exception, or software exception.<sup>1</sup>

In all the above cases, this field receives the length in bytes (1–15) of the instruction (including any instruction prefixes) whose execution led to the VM exit (see the next paragraph for one exception).

The cases of VM exits encountered during delivery of a software interrupt, privileged software exception, or software exception include those encountered during delivery of events injected as part of VM entry (see Section 23.5.1.2). If the original event was injected as part of VM entry, this field receives the value of the VM-entry instruction length.

All VM exits other than those listed in the above items leave this field undefined.

- **VM-exit instruction information.** For VM exits due to attempts to execute INS, INVEPT, INVPID, LIDT, LGDT, LLDT, LTR, OUTS, SIDT, SGDT, SLDT, STR, VMCLEAR, VMPTRLD, VMPTRST, VMREAD, VMWRITE, or VMXON, this field receives information about the instruction that caused the VM exit. The format of the field depends on the identity of the instruction causing the VM exit:
  - For VM exits due to attempts to execute INS or OUTS, the field has the format is given in Table 24-8.<sup>2</sup>

**Table 24-8. Format of the VM-Exit Instruction-Information Field as Used for INS and OUTS**

| Bit Position(s) | Content                                                                                                                                     |
|-----------------|---------------------------------------------------------------------------------------------------------------------------------------------|
| 6:0             | Undefined.                                                                                                                                  |
| 9:7             | Address size:<br>0: 16-bit<br>1: 32-bit<br>2: 64-bit (used only on processors that support Intel 64 architecture)<br>Other values not used. |
| 14:10           | Undefined.                                                                                                                                  |

- 
1. The VM-exit instruction-length field is not defined following APIC-access VM exits resulting from physical accesses (see Section 22.2.3) even if encountered during delivery of a software interrupt, privileged software exception, or software exception.
  2. The format of the field was undefined for these VM exits on the first processors to support the virtual-machine extensions. Software can determine whether the format specified in Table 24-8 is used by consulting the VMX capability MSR IA32\_VMX\_BASIC (see Appendix G.1).

**Table 24-8. Format of the VM-Exit Instruction-Information Field as Used for INS and OUTS (Contd.)**

| 31:28           | Reg2 (same encoding as IndexReg above)                                                                                                                                                                                                                                          |

For all other VM exits, the field is undefined.

- **I/O RCX, I/O RSI, I/O RDI, I/O RIP.** These fields are undefined except for SMM VM exits due to system-management interrupts (SMIs) that arrive immediately after retirement of I/O instructions. See Section 26.15.2.3.

## 24.3 SAVING GUEST STATE

Each field in the guest-state area of the VMCS (see Section 21.4) is written with the corresponding component of processor state. On processors that support Intel 64 architecture, the full values of each natural-width field (see Section 21.10.2) is saved regardless of the mode of the logical processor before and after the VM exit.

In general, the state saved is that which was in the logical processor at the time the VM exit commences. See Section 24.1 for a discussion of which architectural updates occur at that time.

Section 24.3.1 through Section 24.3.4 provide details for how certain components of processor state are saved. These sections reference VMCS fields that correspond to processor state. Unless otherwise stated, these references are to fields in the guest-state area.

### 24.3.1 Saving Control Registers, Debug Registers, and MSRs

Contents of certain control registers, debug registers, and MSRs is saved as follows:

- The contents of CRO, CR3, CR4, and the IA32\_SYSENTER\_CS, IA32\_SYSENTER\_ESP, and IA32\_SYSENTER\_EIP MSRs are saved into the corresponding fields. Bits 63:32 of the IA32\_SYSENTER\_CS MSR are not saved. On processors that do not support Intel 64 architecture, bits 63:32 of the IA32\_SYSENTER\_ESP and IA32\_SYSENTER\_EIP MSRs are not saved.
- If the “save debug controls” VM-exit control is 1, the contents of DR7 and the IA32\_DEBUGCTL MSR are saved into the corresponding fields. The first processors to support the virtual-machine extensions supported only the 1-setting of this control and thus always saved data into these fields.
- If the “save IA32\_PAT” VM-exit control is 1, the contents of the IA32\_PAT MSR are saved into the corresponding field.
- If the “save IA32\_EFER” VM-exit control is 1, the contents of the IA32\_EFER MSR are saved into the corresponding field.
- The value of the SMBASE field is undefined after all VM exits except SMM VM exits. See Section 26.15.2.

### 24.3.2 Saving Segment Registers and Descriptor-Table Registers

For each segment register (CS, SS, DS, ES, FS, GS, LDTR, or TR), the values saved for the base-address, segment-limit, and access rights are based on whether the register was unusable (see Section 21.4.1) before the VM exit:

- If the register was unusable, the values saved into the following fields are undefined: (1) base address; (2) segment limit; and (3) bits 7:0 and bits 15:12 in the access-rights field. The following exceptions apply:
  - CS.
    - The base-address and segment-limit fields are saved.
    - The L, D, and G bits are saved in the access-rights field.
  - SS.
    - DPL is saved in the access-rights field.
    - On processors that support Intel 64 architecture, bits 63:32 of the value saved for the base address are always zero.
  - DS and ES. On processors that support Intel 64 architecture, bits 63:32 of the values saved for the base addresses are always zero.
  - FS and GS. The base-address field is saved.
  - LDTR. The value saved for the base address is always canonical.

## VM EXITS

- If the register was not unusable, the values saved into the following fields are those which were in the register before the VM exit: (1) base address; (2) segment limit; and (3) bits 7:0 and bits 15:12 in access rights.
- Bits 31:17 and 11:8 in the access-rights field are always cleared. Bit 16 is set to 1 if and only if the segment is unusable.

The contents of the GDTR and IDTR registers are saved into the corresponding base-address and limit fields.

### 24.3.3 Saving RIP, RSP, and RFLAGS

The contents of the RIP, RSP, and RFLAGS registers are saved as follows:

- The value saved in the RIP field is determined by the nature and cause of the VM exit:
  - If the VM exit occurs due to an attempt to execute an instruction that causes VM exits unconditionally or that has been configured to cause a VM exit via the VM-execution controls, the value saved references that instruction.
  - If the VM exit is caused by an occurrence of an INIT signal, a start-up IPI (SIP), or system-management interrupt (SMI), the value saved is that which was in RIP before the event occurred.
  - If the VM exit occurs due to the 1-setting of either the “interrupt-window exiting” VM-execution control or the “NMI-window exiting” VM-execution control, the value saved is that which would be in the register had the VM exit not occurred.
  - If the VM exit is due to an external interrupt, non-maskable interrupt (NMI), or hardware exception (as defined in Section 24.2.2), the value saved is the return pointer that would have been saved (either on the stack had the event been delivered through a trap or interrupt gate,<sup>1</sup> or into the old task-state segment had the event been delivered through a task gate).
  - If the VM exit is due to a triple fault, the value saved is the return pointer that would have been saved (either on the stack had the event been delivered through a trap or interrupt gate, or into the old task-state segment had the event been delivered through a task gate) had delivery of the double fault not encountered the nested exception that caused the triple fault.
  - If the VM exit is due to a software exception (due to an execution of INT3 or INTO), the value saved references the INT3 or INTO instruction that caused that exception.
  - Suppose that the VM exit is due to a task switch that was caused by execution of CALL, IRET, or JMP or by execution of a software interrupt (INT *n*) or

---

1. The reference here is to the full value of RIP before any truncation that would occur had the stack width been only 32 bits or 16 bits.

software exception (due to execution of INT3 or INTO) that encountered a task gate in the IDT. The value saved references the instruction that caused the task switch (CALL, IRET, JMP, INT *n*, INT3, or INTO).

- Suppose that the VM exit is due to a task switch that was caused by a task gate in the IDT that was encountered for any reason except the direct access by a software interrupt or software exception. The value saved is that which would have been saved in the old task-state segment had the task switch completed normally.
- If the VM exit is due to an execution of MOV to CR8 or WRMSR that reduced the value of the TPR shadow<sup>1</sup> below that of TPR threshold VM-execution control field, the value saved references the instruction following the MOV to CR8 or WRMSR.
- If the VM exit was caused by a TPR-shadow update (see Section 21.5.3.3) that results from an APIC access as part of instruction execution, the value saved references the instruction following the one whose execution caused the VTPR access.
- The contents of the RSP register are saved into the RSP field.
- With the exception of the resume flag (RF; bit 16), the contents of the RFLAGS register is saved into the RFLAGS field. RFLAGS.RF is saved as follows:
  - If the VM exit is caused directly by an event that would normally be delivered through the IDT, the value saved is that which would appear in the saved RFLAGS image (either that which would be saved on the stack had the event been delivered through a trap or interrupt gate<sup>2</sup> or into the old task-state segment had the event been delivered through a task gate) had the event been delivered through the IDT. See below for VM exits due to task switches caused by task gates in the IDT.
  - If the VM exit is caused by a triple fault, the value saved is that which the logical processor would have in RF in the RFLAGS register had the triple fault taken the logical processor to the shutdown state.
  - If the VM exit is caused by a task switch (including one caused by a task gate in the IDT), the value saved is that which would have been saved in the RFLAGS image in the old task-state segment (TSS) had the task switch completed normally without exception.
  - If the VM exit is caused by an attempt to execute an instruction that unconditionally causes VM exits or one that was configured to do with a VM-execution control, the value saved is 0.<sup>3</sup>

---

1. The TPR shadow is bits 7:4 of the byte at offset 80H of the virtual-APIC page (see Section 21.6.8).  
 2. The reference here is to the full value of RFLAGS before any truncation that would occur had the stack width been only 32 bits or 16 bits.

## VM EXITS

- For APIC-access VM exits and for VM exits caused by EPT violations and EPT misconfigurations, the value saved depends on whether the VM exit occurred during delivery of an event through the IDT:
  - If the VM exit stored 0 for bit 31 for IDT-vectoring information field (because the VM exit did not occur during delivery of an event through the IDT; see Section 24.2.3), the value saved is 1.
  - If the VM exit stored 1 for bit 31 for IDT-vectoring information field (because the VM exit did occur during delivery of an event through the IDT), the value saved is the value that would have appeared in the saved RFLAGS image had the event been delivered through the IDT (see above).
- For all other VM exits, the value saved is the value RFLAGS.RF had before the VM exit occurred.

### 24.3.4 Saving Non-Register State

Information corresponding to guest non-register state is saved as follows:

- The activity-state field is saved with the logical processor’s activity state before the VM exit.<sup>1</sup> See Section 24.1 for details of how events leading to a VM exit may affect the activity state.
- The interruptibility-state field is saved to reflect the logical processor’s interruptibility before the VM exit. See Section 24.1 for details of how events leading to a VM exit may affect this state. VM exits that end outside system-management mode (SMM) save bit 2 (blocking by SMI) as 0 regardless of the state of such blocking before the VM exit.  
Bit 3 (blocking by NMI) is treated specially if the “virtual NMIs” VM-execution control is 1. In this case, the value saved for this field does not indicate the blocking of NMIs but rather the state of virtual-NMI blocking.
- The pending debug exceptions field is saved as clear for all VM exits except the following:
  - A VM exit caused by an INIT signal, a machine-check exception, or a system-management interrupt (SMI).
  - A VM exit with basic exit reason either “TPR below threshold.”<sup>2</sup>
  - A VM exit with basic exit reason “monitor trap flag.”

- 
3. This is true even if RFLAGS.RF was 1 before the instruction was executed. If, in response to such a VM exit, a VM monitor re-enters the guest to re-execute the instruction that caused the VM exit (for example, after clearing the VM-execution control that caused the VM exit), the instruction may encounter a code breakpoint that has already been processed. A VM monitor can avoid this by setting the guest value of RFLAGS.RF to 1 before resuming guest software.
  1. If this activity state was an inactive state resulting from execution of a specific instruction (HLT or MWAIT), the value saved for RIP by that VM exit will reference the following instruction.

- VM exits that are not caused by debug exceptions and that occur while there is MOV-SS blocking of debug exceptions.

For VM exits that do not clear the field, the value saved is determined as follows:

- Each of bits 3:0 may be set if it corresponds to a matched breakpoint. This may be true even if the corresponding breakpoint is not enabled in DR7.
- Suppose that a VM exit is due to an INIT signal, a machine-check exception, or an SMI; or that a VM exit has basic exit reason “TPR below threshold” or “monitor trap flag.” In this case, the value saved sets bits corresponding to the causes of any debug exceptions that were pending at the time of the VM exit.

If the VM exit occurs immediately after VM entry, the value saved may match that which was loaded on VM entry (see Section 23.6.3). Otherwise, the following items apply:

- Bit 12 (enabled breakpoint) is set to 1 if there was at least one matched data or I/O breakpoint that was enabled in DR7. Bit 12 is also set if it had been set on VM entry, causing there to be valid pending debug exceptions (see Section 23.6.3) and the VM exit occurred before those exceptions were either delivered or lost. In other cases, bit 12 is cleared to 0.
- Bit 14 (BS) is set if RFLAGS.TF = 1 in either of the following cases:
  - IA32\_DEBUGCTL.BTF = 0 and the cause of a pending debug exception was the execution of a single instruction.
  - IA32\_DEBUGCTL.BTF = 1 and the cause of a pending debug exception was a taken branch.
- Suppose that a VM exit is due to another reason (but not a debug exception) and occurs while there is MOV-SS blocking of debug exceptions. In this case, the value saved sets bits corresponding to the causes of any debug exceptions that were pending at the time of the VM exit. If the VM exit occurs immediately after VM entry (no instructions were executed in VMX non-root operation), the value saved may match that which was loaded on VM entry (see Section 23.6.3). Otherwise, the following items apply:
  - Bit 12 (enabled breakpoint) is set to 1 if there was at least one matched data or I/O breakpoint that was enabled in DR7. Bit 12 is also set if it had been set on VM entry, causing there to be valid pending debug exceptions (see Section 23.6.3) and the VM exit occurred before those exceptions were either delivered or lost. In other cases, bit 12 is cleared to 0.
  - The setting of bit 14 (BS) is implementation-specific. However, it is not set if RFLAGS.TF = 0 or IA32\_DEBUGCTL.BTF = 1.
  - The reserved bits in the field are cleared.

---

2. This item includes VM exits that occur after executions of MOV to CR8 or WRMSR (Section 22.1.3), TPR-shadow updates (Section 22.5.3.3), and certain VM entries (Section 23.6.7).

## VM EXITS

- If the “save VMX-preemption timer value” VM-exit control is 1, the value of timer is saved into the VMX-preemption timer-value field. This is the value loaded from this field on VM entry as subsequently decremented (see Section 22.7.1). VM exits due to timer expiration save the value 0. Other VM exits may also save the value 0 if the timer expired during VM exit. (If the “save VMX-preemption timer value” VM-exit control is 0, VM exit does not modify the value of the VMX-preemption timer-value field.)
- If the logical processor supports the 1-setting of the “enable EPT” VM-execution control, values are saved into the four (4) PDPTE fields as follows:
  - If the “enable EPT” VM-execution control is 1 and the logical processor was using PAE paging at the time of the VM exit, the PDPTE values currently in use are saved:<sup>1</sup>
    - The values saved into bits 11:9 of each of the fields is undefined.
    - If the value saved into one of the fields has bit 0 (present) clear, the value saved into bits 63:1 of that field is undefined. That value need not correspond to the value that was loaded by VM entry or to any value that might have been loaded in VMX non-root operation.
    - If the value saved into one of the fields has bit 0 (present) set, the value saved into bits 63:12 of the field is a guest-physical address.
  - If the “enable EPT” VM-execution control is 0 or the logical processor was not using PAE paging at the time of the VM exit, the values saved are undefined.

## 24.4 SAVING MSRS

After processor state is saved to the guest-state area, values of MSRs may be stored into the VM-exit MSR-store area (see Section 21.7.2). Specifically each entry in that area (up to the number specified in the VM-exit MSR-store count) is processed in order by storing the value of the MSR indexed by bits 31:0 (as they would be read by RDMSR) into bits 127:64. Processing of an entry fails in either of the following cases:

- The value of bits 31:8 is 000008H, meaning that the indexed MSR is one that allows access to an APIC register when the local APIC is in x2APIC mode.
- The value of bits 31:0 indicates an MSR that can be read only in system-management mode (SMM) and the VM exit will not end in SMM.
- The value of bits 31:0 indicates an MSR that cannot be saved on VM exits for model-specific reasons. A processor may prevent certain MSRs (based on the

---

1. A logical processor uses PAE paging if CRO.PG = 1, CR4.PAE = 1 and IA32\_EFER.LMA = 0. See Section 4.4 in the *Intel® 64 and IA-32 Architectures Software Developer’s Manual, Volume 3A*. “Enable EPT” is a secondary processor-based VM-execution control. If bit 31 of the primary processor-based VM-execution controls is 0, VM exit functions as if the “enable EPT” VM-execution control were 0. See Section 21.6.2.

value of bits 31:0) from being stored on VM exits, even if they can normally be read by RDMSR. Such model-specific behavior is documented in Appendix B.

- Bits 63:32 of the entry are not all 0.
- An attempt to read the MSR indexed by bits 31:0 would cause a general-protection exception if executed via RDMSR with CPL = 0.

A VMX abort occurs if processing fails for any entry. See Section 24.7.

## 24.5 LOADING HOST STATE

Processor state is updated on VM exits in the following ways:

- Some state is loaded from or otherwise determined by the contents of the host-state area.
- Some state is determined by VM-exit controls.
- Some state is established in the same way on every VM exit.
- The page-directory pointers are loaded based on the values of certain control registers.

This loading may be performed in any order.

On processors that support Intel 64 architecture, the full values of each 64-bit field loaded (for example, the base address for GDTR) is loaded regardless of the mode of the logical processor before and after the VM exit.

The loading of host state is detailed in Section 24.5.1 to Section 24.5.5. These sections reference VMCS fields that correspond to processor state. Unless otherwise stated, these references are to fields in the host-state area.

A logical processor is in IA-32e mode after a VM exit only if the “host address-space size” VM-exit control is 1. If the logical processor was in IA-32e mode before the VM exit and this control is 0, a VMX abort occurs. See Section 24.7.

In addition to loading host state, VM exits clear address-range monitoring (Section 24.5.6).

After the state loading described in this section, VM exits may load MSRs from the VM-exit MSR-load area (see Section 24.6). This loading occurs only after the state loading described in this section.

### 24.5.1 Loading Host Control Registers, Debug Registers, MSRs

VM exits load new values for controls registers, debug registers, and some MSRs:

- CRO, CR3, and CR4 are loaded from the CRO field, the CR3 field, and the CR4 field, respectively, with the following exceptions:
  - The following bits are not modified:

## VM EXITS

- For CRO, ET, CD, NW; bits 63:32 (on processors that support Intel 64 architecture), 28:19, 17, and 15:6; and any bits that are fixed in VMX operation (see Section 20.8).<sup>1</sup>
  - For CR3, bits 63:52 and bits in the range 51:32 beyond the processor’s physical-address width (they are cleared to 0).<sup>2</sup> (This item applies only to processors that support Intel 64 architecture.)
  - For CR4, any bits that are fixed in VMX operation (see Section 20.8).
    - CR4.PAE is set to 1 if the “host address-space size” VM-exit control is 1.
    - CR4.PCIDE is set to 0 if the “host address-space size” VM-exit control is 0.
  - DR7 is set to 400H.
  - The following MSRs are established as follows:
    - The IA32\_DEBUGCTL MSR is cleared to 00000000\_00000000H.
    - The IA32\_SYSENTER\_CS MSR is loaded from the IA32\_SYSENTER\_CS field. Since that field has only 32 bits, bits 63:32 of the MSR are cleared to 0.
    - IA32\_SYSENTER\_ESP MSR and IA32\_SYSENTER\_EIP MSR are loaded from the IA32\_SYSENTER\_ESP field and the IA32\_SYSENTER\_EIP field, respectively.
- If the processor does not support the Intel 64 architecture, these fields have only 32 bits; bits 63:32 of the MSRs are cleared to 0.
- If the processor does support the Intel 64 architecture and the processor supports  $N < 64$  linear-address bits, each of bits 63:N is set to the value of bit N-1.<sup>3</sup>
- The following steps are performed on processors that support Intel 64 architecture:
    - The MSRs FS.base and GS.base are loaded from the base-address fields for FS and GS, respectively (see Section 24.5.2).
    - The LMA and LME bits in the IA32\_EFER MSR are each loaded with the setting of the “host address-space size” VM-exit control.
  - If the “load IA32\_PERF\_GLOBAL\_CTRL” VM-exit control is 1, the IA32\_PERF\_GLOBAL\_CTRL MSR is loaded from the IA32\_PERF\_GLOBAL\_CTRL field. Bits that are reserved in that MSR are maintained with their reserved values.

- 
1. Bits 28:19, 17, and 15:6 of CRO and CRO.ET are unchanged by executions of MOV to CRO. CRO.ET is always 1 and the other bits are always 0.
  2. Software can determine a processor’s physical-address width by executing CPUID with 80000008H in EAX. The physical-address width is returned in bits 7:0 of EAX.
  3. Software can determine the number N by executing CPUID with 80000008H in EAX. The number of linear-address bits supported is returned in bits 15:8 of EAX.

- If the “load IA32\_PAT” VM-exit control is 1, the IA32\_PAT MSR is loaded from the IA32\_PAT field. Bits that are reserved in that MSR are maintained with their reserved values.
- If the “load IA32\_EFER” VM-exit control is 1, the IA32\_EFER MSR is loaded from the IA32\_EFER field. Bits that are reserved in that MSR are maintained with their reserved values.

With the exception of FS.base and GS.base, any of these MSRs is subsequently overwritten if it appears in the VM-exit MSR-load area. See Section 24.6.

### 24.5.2 Loading Host Segment and Descriptor-Table Registers

Each of the registers CS, SS, DS, ES, FS, GS, and TR is loaded as follows (see below for the treatment of LDTR):

- The selector is loaded from the selector field. The segment is unusable if its selector is loaded with zero. The checks specified Section 23.3.1.2 limit the selector values that may be loaded. In particular, CS and TR are never loaded with zero and are thus never unusable. SS can be loaded with zero only on processors that support Intel 64 architecture and only if the VM exit is to 64-bit mode (64-bit mode allows use of segments marked unusable).
- The base address is set as follows:
  - CS. Cleared to zero.
  - SS, DS, and ES. Undefined if the segment is unusable; otherwise, cleared to zero.
  - FS and GS. Undefined (but, on processors that support Intel 64 architecture, canonical) if the segment is unusable and the VM exit is not to 64-bit mode; otherwise, loaded from the base-address field.

If the processor supports the Intel 64 architecture and the processor supports  $N < 64$  linear-address bits, each of bits 63:N is set to the value of bit N-1.<sup>1</sup> The values loaded for base addresses for FS and GS are also manifest in the FS.base and GS.base MSRs.
- TR. Loaded from the host-state area. If the processor supports the Intel 64 architecture and the processor supports  $N < 64$  linear-address bits, each of bits 63:N is set to the value of bit N-1.
- The segment limit is set as follows:
  - CS. Set to FFFFFFFFH (corresponding to a descriptor limit of FFFFH and a G-bit setting of 1).
  - SS, DS, ES, FS, and GS. Undefined if the segment is unusable; otherwise, set to FFFFFFFFH.

---

1. Software can determine the number N by executing CPUID with 80000008H in EAX. The number of linear-address bits supported is returned in bits 15:8 of EAX.

## VM EXITS

- TR. Set to 00000067H.
- The type field and S bit are set as follows:
  - CS. Type set to 11 and S set to 1 (execute/read, accessed, non-conforming code segment).
  - SS, DS, ES, FS, and GS. Undefined if the segment is unusable; otherwise, type set to 3 and S set to 1 (read/write, accessed, expand-up data segment).
  - TR. Type set to 11 and S set to 0 (busy 32-bit task-state segment).
- The DPL is set as follows:
  - CS, SS, and TR. Set to 0. The current privilege level (CPL) will be 0 after the VM exit completes.
  - DS, ES, FS, and GS. Undefined if the segment is unusable; otherwise, set to 0.
- The P bit is set as follows:
  - CS, TR. Set to 1.
  - SS, DS, ES, FS, and GS. Undefined if the segment is unusable; otherwise, set to 1.
- On processors that support Intel 64 architecture, CS.L is loaded with the setting of the “host address-space size” VM-exit control. Because the value of this control is also loaded into IA32\_EFER.LMA (see Section 24.5.1), no VM exit is ever to compatibility mode (which requires IA32\_EFER.LMA = 1 and CS.L = 0).
- D/B.
  - CS. Loaded with the inverse of the setting of the “host address-space size” VM-exit control. For example, if that control is 0, indicating a 32-bit guest, CS.D/B is set to 1.
  - SS. Set to 1.
  - DS, ES, FS, and GS. Undefined if the segment is unusable; otherwise, set to 1.
  - TR. Set to 0.
- G.
  - CS. Set to 1.
  - SS, DS, ES, FS, and GS. Undefined if the segment is unusable; otherwise, set to 1.
  - TR. Set to 0.

The host-state area does not contain a selector field for LDTR. LDTR is established as follows on all VM exits: the selector is cleared to 0000H, the segment is marked unusable and is otherwise undefined (although the base address is always canonical).

The base addresses for GDTR and IDTR are loaded from the GDTR base-address field and the IDTR base-address field, respectively. If the processor supports the Intel 64 architecture and the processor supports  $N < 64$  linear-address bits, each of bits 63:N of each base address is set to the value of bit N-1 of that base address. The GDTR and IDTR limits are each set to FFFFH.

### 24.5.3 Loading Host RIP, RSP, and RFLAGS

RIP and RSP are loaded from the RIP field and the RSP field, respectively. RFLAGS is cleared, except bit 1, which is always set.

### 24.5.4 Checking and Loading Host Page-Directory-Pointer-Table Entries

If CRO.PG = 1, CR4.PAE = 1, and IA32\_EFER.LMA = 0, the logical processor uses **PAE paging**. See Section 4.4 of the *Intel® 64 and IA-32 Architectures Software Developer’s Manual, Volume 3A*.<sup>1</sup> When in PAE paging is in use, the physical address in CR3 references a table of **page-directory-pointer-table entries** (PDPTes). A MOV to CR3 when PAE paging is in use checks the validity of the PDPTes and, if they are valid, loads them into the processor (into internal, non-architectural registers).

A VM exit is to a VMM that uses PAE paging if (1) bit 5 (corresponding to CR4.PAE) is set in the CR4 field in the host-state area of the VMCS; and (2) the “host address-space size” VM-exit control is 0. Such a VM exit may check the validity of the PDPTes referenced by the CR3 field in the host-state area of the VMCS. Such a VM exit must check their validity if either (1) PAE paging was not in use before the VM exit; or (2) the value of CR3 is changing as a result of the VM exit. A VM exit to a VMM that does not use PAE paging must not check the validity of the PDPTes.

A VM exit that checks the validity of the PDPTes uses the same checks that are used when CR3 is loaded with MOV to CR3 when PAE paging is in use. If MOV to CR3 would cause a general-protection exception due to the PDPTes that would be loaded (e.g., because a reserved bit is set), a VMX abort occurs (see Section 24.7). If a VM exit to a VMM that uses PAE does not cause a VMX abort, the PDPTes are loaded into the processor as would MOV to CR3, using the value of CR3 being load by the VM exit.

### 24.5.5 Updating Non-Register State

VM exits affect the non-register state of a logical processor as follows:

- A logical processor is always in the active state after a VM exit.

1. On processors that support Intel 64 architecture, the physical-address extension may support more than 36 physical-address bits. Software can determine a processor’s physical-address width by executing CPUID with 80000008H in EAX. The physical-address width is returned in bits 7:0 of EAX.

## VM EXITS

- Event blocking is affected as follows:
  - There is no blocking by STI or by MOV SS after a VM exit.
  - VM exits caused directly by non-maskable interrupts (NMIs) cause blocking by NMI (see Table 21-3). Other VM exits do not affect blocking by NMI. (See Section 24.1 for the case in which an NMI causes a VM exit indirectly.)
- There are no pending debug exceptions after a VM exit.

Section 25.3 describes how the VMX architecture controls how a logical processor manages information in the TLBs and paging-structure caches. The following items detail how VM exits invalidate cached mappings:

- If the “enable VPID” VM-execution control is 0, the logical processor invalidates linear mappings and combined mappings associated with VPID 0000H (for all PCIDs); combined mappings for VPID 0000H are invalidated for all EP4TA values (EP4TA is the value of bits 51:12 of EPTP).
- VM exits are not required to invalidate any guest-physical mappings, nor are they required to invalidate any linear mappings or combined mappings if the “enable VPID” VM-execution control is 1.

### 24.5.6 Clearing Address-Range Monitoring

The Intel 64 and IA-32 architectures allow software to monitor a specified address range using the MONITOR and MWAIT instructions. See Section 8.10.4 in the *Intel® 64 and IA-32 Architectures Software Developer’s Manual, Volume 3A*. VM exits clear any address-range monitoring that may be in effect.

## 24.6 LOADING MSRS

VM exits may load MSRs from the VM-exit MSR-load area (see Section 21.7.2). Specifically each entry in that area (up to the number specified in the VM-exit MSR-load count) is processed in order by loading the MSR indexed by bits 31:0 with the contents of bits 127:64 as they would be written by WRMSR.

Processing of an entry fails in any of the following cases:

- The value of bits 31:0 is either C0000100H (the IA32\_FS\_BASE MSR) or C0000101H (the IA32\_GS\_BASE MSR).
- The value of bits 31:8 is 000008H, meaning that the indexed MSR is one that allows access to an APIC register when the local APIC is in x2APIC mode.
- The value of bits 31:0 indicates an MSR that can be written only in system-management mode (SMM) and the VM exit will not end in SMM. (IA32\_SMM\_MONITOR\_CTL is an MSR that can be written only in SMM.)
- The value of bits 31:0 indicates an MSR that cannot be loaded on VM exits for model-specific reasons. A processor may prevent loading of certain MSRs even if

they can normally be written by WRMSR. Such model-specific behavior is documented in Appendix B.

- Bits 63:32 are not all 0.
- An attempt to write bits 127:64 to the MSR indexed by bits 31:0 of the entry would cause a general-protection exception if executed via WRMSR with CPL = 0.<sup>1</sup>

If processing fails for any entry, a VMX abort occurs. See Section 24.7.

If any MSR is being loaded in such a way that would architecturally require a TLB flush, the TLBs are updated so that, after VM exit, the logical processor does not use any translations that were cached before the transition.

## 24.7 VMX ABORTS

A problem encountered during a VM exit leads to a **VMX abort**. A VMX abort takes a logical processor into a shutdown state as described below.

A VMX abort does not modify the VMCS data in the VMCS region of any active VMCS. The contents of these data are thus suspect after the VMX abort.

On a VMX abort, a logical processor saves a nonzero 32-bit VMX-abort indicator field at byte offset 4 in the VMCS region of the VMCS whose misconfiguration caused the failure (see Section 21.2). The following values are used:

1. There was a failure in saving guest MSRs (see Section 24.4).
2. Host checking of the page-directory-pointer-table entries (PDPTEs) failed (see Section 24.5.4).
3. The current VMCS has been corrupted (through writes to the corresponding VMCS region) in such a way that the logical processor cannot complete the VM exit properly.
4. There was a failure on loading host MSRs (see Section 24.6).
5. There was a machine check during VM exit (see Section 24.8).
6. The logical processor was in IA-32e mode before the VM exit and the “host address-space size” VM-entry control was 0 (see Section 24.5).

Some of these causes correspond to failures during the loading of state from the host-state area. Because the loading of such state may be done in any order (see Section 24.5) a VM exit that might lead to a VMX abort for multiple reasons (for example, the current VMCS may be corrupt and the host PDPTEs might not be prop-

---

1. Note the following about processors that support Intel 64 architecture. If CRO.PG = 1, WRMSR to the IA32\_EFER MSR causes a general-protection exception if it would modify the LME bit. Since CRO.PG is always 1 in VMX operation, the IA32\_EFER MSR should not be included in the VM-exit MSR-load area for the purpose of modifying the LME bit.

## VM EXITS

erly configured). In such cases, the VMX-abort indicator could correspond to any one of those reasons.

A logical processor never reads the VMX-abort indicator in a VMCS region and writes it only with one of the non-zero values mentioned above. The VMX-abort indicator allows software on one logical processor to diagnose the VMX-abort on another. For this reason, it is recommended that software running in VMX root operation zero the VMX-abort indicator in the VMCS region of any VMCS that it uses.

After saving the VMX-abort indicator, operation of a logical processor experiencing a VMX abort depends on whether the logical processor is in SMX operation:<sup>1</sup>

- If the logical processor is in SMX operation, an Intel® TXT shutdown condition occurs. The error code used is 000DH, indicating "VMX abort." See *Intel® Trusted Execution Technology Measured Launched Environment Programming Guide*.
- If the logical processor is outside SMX operation, it issues a special bus cycle (to notify the chipset) and enters the **VMX-abort shutdown state**. RESET is the only event that wakes a logical processor from the VMX-abort shutdown state. The following events do not affect a logical processor in this state: machine checks; INIT signals; external interrupts; non-maskable interrupts (NMIs); start-up IPIs (SIPIs); and system-management interrupts (SMIs).

## 24.8 MACHINE CHECK DURING VM EXIT

If a machine check occurs during VM exit, one of the following occurs:

- The machine check is handled normally:
  - If CR4.MCE = 1, a machine-check exception (#MC) delivered through the guest IDT.
  - If CR4.MCE = 0, operation of the logical processor depends on whether the logical processor is in SMX operation:<sup>2</sup>
    - If the logical processor is in SMX operation, an Intel® TXT shutdown condition occurs. The error code used is 000CH, indicating "unrecoverable machine check condition." See *Intel® Trusted Execution Technology Measured Launched Environment Programming Guide*.

- 
1. A logical processor is in SMX operation if GETSEC[SEXIT] has not been executed since the last execution of GETSEC[SENTER]. A logical processor is outside SMX operation if GETSEC[SENTER] has not been executed or if GETSEC[SEXIT] was executed after the last execution of GETSEC[SENTER]. See Chapter 6, "Safer Mode Extensions Reference," in *Intel® 64 and IA-32 Architectures Software Developer's Manual, Volume 2B*.
  2. A logical processor is in SMX operation if GETSEC[SEXIT] has not been executed since the last execution of GETSEC[SENTER]. A logical processor is outside SMX operation if GETSEC[SENTER] has not been executed or if GETSEC[SEXIT] was executed after the last execution of GETSEC[SENTER]. See Chapter 6, "Safer Mode Extensions Reference," in *Intel® 64 and IA-32 Architectures Software Developer's Manual, Volume 2B*.

## VM EXITS

- If the logical processor is outside SMX operation, it goes to the shutdown state.
- A VMX abort is generated (see Section 24.7). The logical processor blocks events as done normally in VMX abort. The VMX abort indicator is 5, for “machine check during VM exit.”

The first option is not used if the machine check occurs after any host state has been loaded.

VM EXITS

## CHAPTER 25

# VMX SUPPORT FOR ADDRESS TRANSLATION

---

The architecture for VMX operation includes two features that support address translation: virtual-processor identifiers (VPIDs) and the extended page-table mechanism (EPT). VPIDs are a mechanism for managing translations of linear addresses. EPT defines a layer of address translation that augments the translation of linear addresses.

Section 25.1 details the architecture of VPIDs. Section 25.2 provides the details of EPT. Section 25.3 explains how a logical processor may cache information from the paging structures, how it may use that cached information, and how software can manage the cached information.

### 25.1 VIRTUAL PROCESSOR IDENTIFIERS (VPIDS)

The original architecture for VMX operation required VMX transitions to flush the TLBs and paging-structure caches. This ensured that translations cached for the old linear-address space would not be used after the transition.

Virtual-processor identifiers (**VPIDs**) introduce to VMX operation a facility by which a logical processor may cache information for multiple linear-address spaces. When VPIDs are used, VMX transitions may retain cached information and the logical processor switches to a different linear-address space.

Section 25.3 details the mechanisms by which a logical processor manages information cached for multiple address spaces. A logical processor may tag some cached information with a 16-bit VPID. This section specifies how the current VPID is determined at any point in time:

- The current VPID is 0000H in the following situations:
  - Outside VMX operation. (This includes operation in system-management mode under the default treatment of SMIs and SMM with VMX operation; see Section 26.14.)
  - In VMX root operation.
  - In VMX non-root operation when the “enable VPID” VM-execution control is 0.
- If the logical processor is in VMX non-root operation and the “enable VPID” VM-execution control is 1, the current VPID is the value of the VPID VM-execution control field in the VMCS. (VM entry ensures that this value is never 0000H; see Section 23.2.1.1.)

VPIDs and PCIDs (see Section 4.10.1) can be used concurrently. When this is done, the processor associates cached information with both a VPID and a PCID. Such

## VMX SUPPORT FOR ADDRESS TRANSLATION

information is used only if the current VPID and PCID **both** match those associated with the cached information.

## 25.2 THE EXTENDED PAGE TABLE MECHANISM (EPT)

The extended page-table mechanism (**EPT**) is a feature that can be used to support the virtualization of physical memory. When EPT is in use, certain addresses that would normally be treated as physical addresses (and used to access memory) are instead treated as **guest-physical addresses**. Guest-physical addresses are translated by traversing a set of **EPT paging structures** to produce physical addresses that are used to access memory.

- Section 25.2.1 gives an overview of EPT.
- Section 25.2.2 describes operation of EPT-based address translation.
- Section 25.2.3 discusses VM exits that may be caused by EPT.
- Section 25.2.4 describes interactions between EPT and memory typing.

### 25.2.1 EPT Overview

EPT is used when the “enable EPT” VM-execution control is 1.<sup>1</sup> It translates the guest-physical addresses used in VMX non-root operation and those used by VM entry for event injection.

The translation from guest-physical addresses to physical addresses is determined by a set of **EPT paging structures**. The EPT paging structures are similar to those used to translate linear addresses while the processor is in IA-32e mode. Section 25.2.2 gives the details of the EPT paging structures.

If CRO.PG = 1, linear addresses are translated through paging structures referenced through control register CR3. While the “enable EPT” VM-execution control is 1, these are called **guest paging structures**. There are no guest paging structures if CRO.PG = 0.<sup>2</sup>

- 
1. “Enable EPT” is a secondary processor-based VM-execution control. If bit 31 of the primary processor-based VM-execution controls is 0, the logical processor operates as if the “enable EPT” VM-execution control were 0. See Section 21.6.2.
  2. If the capability MSR IA32\_VMX\_CRO\_FIXED0 reports that CRO.PG must be 1 in VMX operation, CRO.PG can be 0 in VMX non-root operation only if the “unrestricted guest” VM-execution control and bit 31 of the primary processor-based VM-execution controls are both 1.

When the “enable EPT” VM-execution control is 1, the identity of **guest-physical addresses** depends on the value of CRO.PG:

- If CRO.PG = 0, each linear address is treated as a guest-physical address.
- If CRO.PG = 1, guest-physical addresses are those derived from the contents of control register CR3 and the guest paging structures. (This includes the values of the PDPTEs, which logical processors store in internal, non-architectural registers.) The latter includes (in page-table entries and in other paging-structure entries for which bit 7—PS—is 1) the addresses to which linear addresses are translated by the guest paging structures.

If CRO.PG = 1, the translation of a linear address to a physical address requires multiple translations of guest-physical addresses using EPT. Assume, for example, that CR4.PAE = CR4.PSE = 0. The translation of a 32-bit linear address then operates as follows:

- Bits 31:22 of the linear address select an entry in the guest page directory located at the guest-physical address in CR3. The guest-physical address of the guest page-directory entry (PDE) is translated through EPT to determine the guest PDE’s physical address.
- Bits 21:12 of the linear address select an entry in the guest page table located at the guest-physical address in the guest PDE. The guest-physical address of the guest page-table entry (PTE) is translated through EPT to determine the guest PTE’s physical address.
- Bits 11:0 of the linear address is the offset in the page frame located at the guest-physical address in the guest PTE. The guest-physical address determined by this offset is translated through EPT to determine the physical address to which the original linear address translates.

In addition to translating a guest-physical address to a physical address, EPT specifies the privileges that software is allowed when accessing the address. Attempts at disallowed accesses are called **EPT violations** and cause VM exits. See Section 25.2.3.

A logical processor uses EPT to translate guest-physical addresses only when those addresses are used to access memory. This principle implies the following:

- The MOV to CR3 instruction loads CR3 with a guest-physical address. Whether that address is translated through EPT depends on whether PAE paging is being used.<sup>1</sup>
  - If PAE paging is not being used, the instruction does not use that address to access memory and does **not** cause it to be translated through EPT. (If CRO.PG = 1, the address will be translated through EPT on the next memory accessing using a linear address.)

---

1. A logical processor uses PAE paging if CRO.PG = 1, CR4.PAE = 1 and IA32\_EFER.LMA = 0. See Section 4.4 in the *Intel® 64 and IA-32 Architectures Software Developer’s Manual, Volume 3A*.

## VMX SUPPORT FOR ADDRESS TRANSLATION

- If PAE paging is being used, the instruction loads the four (4) page-directory-pointer-table entries (PDPTEs) from that address and it **does** cause the address to be translated through EPT.
- The MOV to CR0 instruction establishes PAE paging if it results in CR0.PG = 1 and the following were held before the instruction executed: (1) CR0.PG = 0; (2) CR4.PAE = 1; and (3) IA32\_EFER.LME = 0. Such an execution loads the PDPTEs from the guest-physical address in CR3. The address **is** translated through EPT.
- The MOV to CR4 instruction establishes PAE paging if it results in CR4.PAE = 1 and the following were held before the instruction executed: (1) CR0.PG = 1; (2) CR4.PAE = 0; and (3) IA32\_EFER.LMA = 0. Such an execution loads the PDPTEs from the guest-physical address in CR3. The address **is** translated through EPT.
- The PDPTEs contain guest-physical addresses. The instructions that load the PDPTEs (see above) do not use those addresses to access memory and do **not** cause them to be translated through EPT. (The address in a PDPTE will be translated through EPT on the next memory accessing using a linear address that uses that PDPTE.)

### 25.2.2 EPT Translation Mechanism

The EPT translation mechanism uses only bits 47:0 of each guest-physical address.<sup>1</sup> It uses a page-walk length of 4, meaning that at most 4 EPT paging-structure entries are accessed to translate a guest-physical address.<sup>2</sup>

These 48 bits are partitioned by the logical processor to traverse the EPT paging structures:

- A 4-KByte naturally aligned EPT PML4 table is located at the physical address specified in bits 51:12 of the extended-page-table pointer (EPTP), a VM-execution control field (see Table 21-8 in Section 21.6.11). An EPT PML4 table comprises 512 64-bit entries (EPT PML4Es). An EPT PML4E is selected using the physical address defined as follows:
  - Bits 63:52 are all 0.
  - Bits 51:12 are from the EPTP.
  - Bits 11:3 are bits 47:39 of the guest-physical address.

1. No processors supporting the Intel 64 architecture support more than 48 physical-address bits. Thus, no such processor can produce a guest-physical address with more than 48 bits. An attempt to use such an address causes a page fault. An attempt to load CR3 with such an address causes a general-protection fault. If PAE paging is being used, an attempt to load CR3 that would load a PDPTE with such an address causes a general-protection fault.
2. Future processors may include support for other EPT page-walk lengths. Software should read the VMX capability MSR IA32\_VMX\_EPT\_VPID\_CAP (see Appendix G.10) to determine what EPT page-walk lengths are supported.

- Bits 2:0 are all 0.

Because an EPT PML4E is identified using bits 47:39 of the guest-physical address, it controls access to a 512-GByte region of the guest-physical-address space.

- A 4-KByte naturally aligned EPT page-directory-pointer table is located at the physical address specified in bits 51:12 of the EPT PML4E (see Table 25-1). An EPT page-directory-pointer table comprises 512 64-bit entries (PDPTEs). An EPT PDPTE is selected using the physical address defined as follows:

**Table 25-1. Format of an EPT PML4 Entry (PML4E)**

| Bit Position(s) | Contents                                                                                                             |
|-----------------|----------------------------------------------------------------------------------------------------------------------|
| 0               | Read access; indicates whether reads are allowed from the 512-GByte region controlled by this entry                  |
| 1               | Write access; indicates whether writes are allowed to the 512-GByte region controlled by this entry                  |
| 2               | Execute access; indicates whether instruction fetches are allowed from the 512-GByte region controlled by this entry |
| 7:3             | Reserved (must be 0)                                                                                                 |
| 11:8            | Ignored                                                                                                              |
| (N-1):12        | Physical address of 4-KByte aligned EPT page-directory-pointer table referenced by this entry <sup>1</sup>           |
| 51:N            | Reserved (must be 0)                                                                                                 |
| 63:52           | Ignored                                                                                                              |

**NOTES:**

1. N is the physical-address width supported by the processor. Software can determine a processor's physical-address width by executing CPUID with 80000008H in EAX. The physical-address width is returned in bits 7:0 of EAX.

- Bits 63:52 are all 0.
- Bits 51:12 are from the EPT PML4 entry.
- Bits 11:3 are bits 38:30 of the guest-physical address.
- Bits 2:0 are all 0.

Because a PDPTE is identified using bits 47:30 of the guest-physical address, it controls access to a 1-GByte region of the guest-physical-address space. Use of the PDPTE depends on the value of bit 7 in that entry:<sup>1</sup>

## VMX SUPPORT FOR ADDRESS TRANSLATION

- If bit 7 of the EPT PDPTE is 1, the EPT PDPTE maps a 1-GByte page (see Table 25-2). The final physical address is computed as follows:

**Table 25-2. Format of an EPT Page-Directory-Pointer-Table Entry (PDPTE) that Maps a 1-GByte Page**

| Bit Position(s) | Contents                                                                                                         |
|-----------------|------------------------------------------------------------------------------------------------------------------|
| 0               | Read access; indicates whether reads are allowed from the 1-GByte page referenced by this entry                  |
| 1               | Write access; indicates whether writes are allowed to the 1-GByte page referenced by this entry                  |
| 2               | Execute access; indicates whether instruction fetches are allowed from the 1-GByte page referenced by this entry |
| 5:3             | EPT memory type for this 1-GByte page (see Section 25.2.4)                                                       |
| 6               | Ignore PAT memory type for this 1-GByte page (see Section 25.2.4)                                                |
| 7               | Must be 1 (otherwise, this entry references an EPT page directory)                                               |
| 11:8            | Ignored                                                                                                          |
| 29:12           | Reserved (must be 0)                                                                                             |
| (N-1):30        | Physical address of the 1-GByte page referenced by this entry <sup>1</sup>                                       |
| 51:N            | Reserved (must be 0)                                                                                             |
| 63:52           | Ignored                                                                                                          |

### NOTES:

1. N is the physical-address width supported by the logical processor.
  - Bits 63:52 are all 0.
  - Bits 51:30 are from the EPT PDPTE.
  - Bits 29:0 are from the original guest-physical address.
- If bit 7 of the EPT PDPTE is 0, a 4-KByte naturally aligned EPT page directory is located at the physical address specified in bits 51:12 of the EPT PDPTE (see Table 25-3). An EPT page-directory comprises 512 64-bit entries (PDEs). An EPT PDE is selected using the physical address defined as follows:
  1. Not all processors allow bit 7 of an EPT PDPTE to be set to 1. Software should read the VMX capability MSR IA32\_VMX\_EPT\_VPID\_CAP (see Appendix G.10) to determine whether this is allowed.

**Table 25-3. Format of an EPT Page-Directory-Pointer-Table Entry (PDPT) that References an EPT Page Directory**

| Bit Position(s) | Contents                                                                                                           |
|-----------------|--------------------------------------------------------------------------------------------------------------------|
| 0               | Read access; indicates whether reads are allowed from the 1-GByte region controlled by this entry                  |
| 1               | Write access; indicates whether writes are allowed to the 1-GByte region controlled by this entry                  |
| 2               | Execute access; indicates whether instruction fetches are allowed from the 1-GByte region controlled by this entry |
| 7:3             | Reserved (must be 0)                                                                                               |
| 11:8            | Ignored                                                                                                            |
| (N-1):12        | Physical address of 4-KByte aligned EPT page directory referenced by this entry <sup>1</sup>                       |
| 51:N            | Reserved (must be 0)                                                                                               |
| 63:52           | Ignored                                                                                                            |

**NOTES:**

1. N is the physical-address width supported by the logical processor.

- Bits 63:52 are all 0.
- Bits 51:12 are from the EPT PDPT.
- Bits 11:3 are bits 29:21 of the guest-physical address.
- Bits 2:0 are all 0.

Because an EPT PDE is identified using bits 47:21 of the guest-physical address, it controls access to a 2-MByte region of the guest-physical-address space. Use of the EPT PDE depends on the value of bit 7 in that entry:

- If bit 7 of the EPT PDE is 1, the EPT PDE maps a 2-MByte page (see Table 25-4). The final physical address is computed as follows:
  - Bits 63:52 are all 0.
  - Bits 51:21 are from the EPT PDE.
  - Bits 20:0 are from the original guest-physical address.
- If bit 7 of the EPT PDE is 0, a 4-KByte naturally aligned EPT page table is located at the physical address specified in bits 51:12 of the EPT PDE (see Table 25-5). An EPT page table comprises 512 64-bit entries (PTEs). An EPT PTE is selected using a physical address defined as follows:
  - Bits 63:52 are all 0.

## VMX SUPPORT FOR ADDRESS TRANSLATION

**Table 25-4. Format of an EPT Page-Directory Entry (PDE) that Maps a 2-MByte Page**

| Bit Position(s) | Contents                                                                                                         |
|-----------------|------------------------------------------------------------------------------------------------------------------|
| 0               | Read access; indicates whether reads are allowed from the 2-MByte page referenced by this entry                  |
| 1               | Write access; indicates whether writes are allowed to the 2-MByte page referenced by this entry                  |
| 2               | Execute access; indicates whether instruction fetches are allowed from the 2-MByte page referenced by this entry |
| 5:3             | EPT memory type for this 2-MByte page (see Section 25.2.4)                                                       |
| 6               | Ignore PAT memory type for this 2-MByte page (see Section 25.2.4)                                                |
| 7               | Must be 1 (otherwise, this entry references an EPT page table)                                                   |
| 11:8            | Ignored                                                                                                          |
| 20:12           | Reserved (must be 0)                                                                                             |
| (N-1):21        | Physical address of the 2-MByte page referenced by this entry <sup>1</sup>                                       |
| 51:N            | Reserved (must be 0)                                                                                             |
| 63:52           | Ignored                                                                                                          |

**NOTES:**

1. N is the physical-address width supported by the logical processor.

- Bits 51:12 are from the EPT PDE.
- Bits 11:3 are bits 20:12 of the guest-physical address.
- Bits 2:0 are all 0.
- Because an EPT PTE is identified using bits 47:12 of the guest-physical address, every EPT PTE maps a 4-KByte page (see Table 25-6). The final physical address is computed as follows:
  - Bits 63:52 are all 0.
  - Bits 51:12 are from the EPT PTE.
  - Bits 11:0 are from the original guest-physical address.

If bits 2:0 of an EPT paging-structure entry are all 0, the entry is **not present**. The processor ignores bits 63:3 and does not use the entry either to reference another EPT paging-structure entry nor to produce a physical address. A reference using a guest-physical address whose translation encounters an EPT paging-structure that is not present causes an EPT violation (see Section 25.2.3.2).

**Table 25-5. Format of an EPT Page-Directory Entry (PDE) that References an EPT Page Table**

| Bit Position(s) | Contents                                                                                                           |
|-----------------|--------------------------------------------------------------------------------------------------------------------|
| 0               | Read access; indicates whether reads are allowed from the 2-MByte region controlled by this entry                  |
| 1               | Write access; indicates whether writes are allowed to the 2-MByte region controlled by this entry                  |
| 2               | Execute access; indicates whether instruction fetches are allowed from the 2-MByte region controlled by this entry |
| 6:3             | Reserved (must be 0)                                                                                               |
| 7               | Must be 0 (otherwise, this entry maps a 2-MByte page)                                                              |
| 11:8            | Ignored                                                                                                            |
| (N-1):12        | Physical address of 4-KByte aligned EPT page table referenced by this entry <sup>1</sup>                           |
| 51:N            | Reserved (must be 0)                                                                                               |
| 63:52           | Ignored                                                                                                            |

**NOTES:**

1. N is the physical-address width supported by the logical processor.

The discussion above describes how the EPT paging structures reference each other and how the logical processor traverses those structures when translating a guest-physical address. It does not cover all details of the translation process. Additional details are provided as follows:

- Situations in which the translation process may lead to VM exits (sometimes before the process completes) are described in Section 25.2.3.
- Interactions between the EPT translation mechanism and memory typing are described in Section 25.2.4.

Figure 25-1 gives a summary of the formats of the EPTP and the EPT paging-structure entries. For the EPT paging structure entries, it identifies separately the format of entries that map pages, those that reference other EPT paging structures, and those that do neither because they are “not present”; bits 2:0 and bit 7 are highlighted because they determine how a paging-structure entry is used.

## VMX SUPPORT FOR ADDRESS TRANSLATION

Table 25-6. Format of an EPT Page-Table Entry

| Bit Position(s) | Contents                                                                                                         |
|-----------------|------------------------------------------------------------------------------------------------------------------|
| 0               | Read access; indicates whether reads are allowed from the 4-KByte page referenced by this entry                  |
| 1               | Write access; indicates whether writes are allowed to the 4-KByte page referenced by this entry                  |
| 2               | Execute access; indicates whether instruction fetches are allowed from the 4-KByte page referenced by this entry |
| 5:3             | EPT memory type for this 4-KByte page (see Section 25.2.4)                                                       |
| 6               | Ignore PAT memory type for this 4-KByte page (see Section 25.2.4)                                                |
| 11:7            | Ignored                                                                                                          |
| (N-1):12        | Physical address of the 4-KByte page referenced by this entry <sup>1</sup>                                       |
| 51:N            | Reserved (must be 0)                                                                                             |
| 63:52           | Ignored                                                                                                          |

NOTES:

1. N is the physical-address width supported by the logical processor.

### 25.2.3 EPT-Induced VM Exits

Accesses using guest-physical addresses may cause VM exits due to **EPT misconfigurations** and **EPT violations**. An EPT misconfiguration occurs when, in the course of translation a guest-physical address, the logical processor encounters an EPT paging-structure entry that contains an unsupported value. An EPT violation occurs when there is no EPT misconfiguration but the EPT paging-structure entries disallow an access using the guest-physical address.

EPT misconfigurations and EPT violations occur only due to an attempt to access memory with a guest-physical address. Loading CR3 with a guest-physical address with the MOV to CR3 instruction can cause neither an EPT configuration nor an EPT violation until that address is used to access a paging structure.<sup>1</sup>

---

1. If the logical processor is using PAE paging—because CR0.PG = CR4.PAE = 1 and IA32\_EFER.LMA = 0—the MOV to CR3 instruction loads the PDPTEs from memory using the guest-physical address being loaded into CR3. In this case, therefore, the MOV to CR3 instruction may cause an EPT misconfiguration or an EPT violation.

Figure 25-1. Formats of EPTP and EPT Paging-Structure Entries

**NOTES:**

1. M is an abbreviation for MAXPHYADDR.
2. See Section 21.6.11 for details of the EPTP.

## VMX SUPPORT FOR ADDRESS TRANSLATION

### 25.2.3.1 EPT Misconfigurations

AN EPT misconfiguration occurs if any of the following is identified while translating a guest-physical address:

- The value of bits 2:0 of an EPT paging-structure entry is either 010b (write-only) or 110b (write/execute).
- The value of bits 2:0 of an EPT paging-structure entry is 100b (execute-only) and this value is not supported by the logical processor. Software should read the VMX capability MSR IA32\_VMX\_EPT\_VPID\_CAP to determine whether this value is supported (see Appendix G.10).
- The value of bits 2:0 of an EPT paging-structure entry is not 000b (the entry is present) **and** one of the following holds:
  - A reserved bit is set. This includes the setting of a bit in the range 51:12 that is beyond the logical processor's physical-address width.<sup>1</sup> See Section 25.2.2 for details of which bits are reserved in which EPT paging-structure entries.
  - The entry is the last one used to translate a guest physical address (either an EPT PDE with bit 7 set to 1 or an EPT PTE) and the value of bits 5:3 (EPT memory type) is 2, 3, or 7 (these values are reserved).

EPT misconfigurations result when an EPT paging-structure entry is configured with settings reserved for future functionality. Software developers should be aware that such settings may be used in the future and that an EPT paging-structure entry that causes an EPT misconfiguration on one processor might not do so in the future.

### 25.2.3.2 EPT Violations

An EPT violation may occur during an access using a guest-physical address whose translation does not cause an EPT misconfiguration. An EPT violation occurs in any of the following situations:

- Translation of the guest-physical address encounters an EPT paging-structure entry that is not present (see Section 25.2.2).
- The access is a data read and bit 0 was clear in any of the EPT paging-structure entries used to translate the guest-physical address. Reads by the logical processor of guest paging structures to translate a linear address are considered to be data reads.
- The access is a data write and bit 1 was clear in any of the EPT paging-structure entries used to translate the guest-physical address. Writes by the logical processor to guest paging structures to update accessed and dirty flags are considered to be data writes.
- The access is an instruction fetch and bit 2 was clear in any of the EPT paging-structure entries used to translate the guest-physical address.

---

1. Software can determine a processor's physical-address width by executing CPUID with 80000008H in EAX. The physical-address width is returned in bits 7:0 of EAX.

### 25.2.3.3 Prioritization of EPT-Induced VM Exits

The translation of a linear address to a physical address requires one or more translations of guest-physical addresses using EPT (see Section 25.2.1). This section specifies the relative priority of EPT-induced VM exits with respect to each other and to other events that may be encountered when accessing memory using a linear address.

For an access to a guest-physical address, determination of whether an EPT misconfiguration or an EPT violation occurs is based on an iterative process:<sup>1</sup>

1. An EPT paging-structure entry is read (initially, this is an EPT PML4 entry):
  - a. If the entry is not present (bits 2:0 are all 0), an EPT violation occurs.
  - b. If the entry is present but its contents are not configured properly (see Section 25.2.3.1), an EPT misconfiguration occurs.
  - c. If the entry is present and its contents are configured properly, operation depends on whether the entry references another EPT paging structure (whether it is an EPT PDE with bit 7 set to 1 or an EPT PTE):
    - i) If the entry does reference another EPT paging structure, an entry from that structure is accessed; step 1 is executed for that other entry.
    - ii) Otherwise, the entry is used to produce the ultimate physical address (the translation of the original guest-physical address); step 2 is executed.
2. Once the ultimate physical address is determined, the privileges determined by the EPT paging-structure entries are evaluated:
  - a. If the access to the guest-physical address is not allowed by these privileges (see Section 25.2.3.2), an EPT violation occurs.
  - b. If the access to the guest-physical address is allowed by these privileges, memory is accessed using the ultimate physical address.

If CR0.PG = 1, the translation of a linear address is also an iterative process, with the processor first accessing an entry in the guest paging structure referenced by the guest-physical address in CR3 (or, if PAE paging is in use, the guest-physical address in the appropriate PDPTE register), then accessing an entry in another guest paging structure referenced by the guest-physical address in the first guest paging-structure entry, etc. Each guest-physical address is itself translated using EPT and may cause an EPT-induced VM exit. The following items detail how page faults and EPT-induced VM exits are recognized during this iterative process:

1. An attempt is made to access a guest paging-structure entry with a guest-physical address (initially, the address in CR3 or PDPTE register).
  - a. If the access fails because of an EPT misconfiguration or an EPT violation (see above), an EPT-induced VM exit occurs.

---

1. This is a simplification of the more detailed description given in Section 25.2.2.

## VMX SUPPORT FOR ADDRESS TRANSLATION

- b. If the access does not cause an EPT-induced VM exit, bit 0 (the present flag) of the entry is consulted:
  - i) If the present flag is 0 or any reserved bit is set, a page fault occurs.
  - ii) If the present flag is 1, no reserved bit is set, operation depends on whether the entry references another guest paging structure (whether it is a guest PDE with PS = 1 or a guest PTE):
    - If the entry does reference another guest paging structure, an entry from that structure is accessed; step 1 is executed for that other entry.
    - Otherwise, the entry is used to produce the ultimate guest-physical address (the translation of the original linear address); step 2 is executed.
2. Once the ultimate guest-physical address is determined, the privileges determined by the guest paging-structure entries are evaluated:
  - a. If the access to the linear address is not allowed by these privileges (e.g., it was a write to a read-only page), a page fault occurs.
  - b. If the access to the linear address is allowed by these privileges, an attempt is made to access memory at the ultimate guest-physical address:
    - i) If the access fails because of an EPT misconfiguration or an EPT violation (see above), an EPT-induced VM exit occurs.
    - ii) If the access does not cause an EPT-induced VM exit, memory is accessed using the ultimate physical address (the translation, using EPT, of the ultimate guest-physical address).

If CRO.PG = 0, a linear address is treated as a guest-physical address and is translated using EPT (see above). This process, if it completes without an EPT violation or EPT misconfiguration, produces a physical address and determines the privileges allowed by the EPT paging-structure entries. If these privileges do not allow the access to the physical address (see Section 25.2.3.2), an EPT violation occurs. Otherwise, memory is accessed using the physical address.

### 25.2.4 EPT and Memory Typing

This section specifies how a logical processor determines the memory type use for a memory access while EPT is in use. (See Chapter 11, “Memory Cache Control” of *Intel® 64 and IA-32 Architectures Software Developer’s Manual, Volume 3A* for details of memory typing in the Intel 64 architecture.) Section 25.2.4.1 explains how the memory type is determined for accesses to the EPT paging structures. Section 25.2.4.2 explains how the memory type is determined for an access using a guest-physical address that is translated using EPT.

#### 25.2.4.1 Memory Type Used for Accessing EPT Paging Structures

This section explains how the memory type is determined for accesses to the EPT paging structures. The determination is based first on the value of bit 30 (cache disable—CD) in control register CR0:

- If CR0.CD = 0, the memory type used for any such reference is the EPT paging-structure memory type, which is specified in bits 2:0 of the extended-page-table pointer (EPTP), a VM-execution control field (see Section 21.6.11). A value of 0 indicates the uncacheable type (UC), while a value of 6 indicates the write-back type (WB). Other values are reserved.
- If CR0.CD = 1, the memory type used for any such reference is uncacheable (UC).

The MTRRs have no effect on the memory type used for an access to an EPT paging structure.

#### 25.2.4.2 Memory Type Used for Translated Guest-Physical Addresses

The **effective memory type** of a memory access using a guest-physical address (an access that is translated using EPT) is the memory type that is used to access memory. The effective memory type is based on the value of bit 30 (cache disable—CD) in control register CR0; the **last** EPT paging-structure entry used to translate the guest-physical address (either an EPT PDE with bit 7 set to 1 or an EPT PTE); and the PAT memory type (see below):

- The **PAT memory type** depends on the value of CR0.PG:
  - If CR0.PG = 0, the PAT memory type is WB (writeback).<sup>1</sup>
  - If CR0.PG = 1, the PAT memory type is the memory type selected from the IA32\_PAT MSR as specified in Section 11.12.3, “Selecting a Memory Type from the PAT”.<sup>2</sup>
- The **EPT memory type** is specified in bits 5:3 of the last EPT paging-structure entry: 0 = UC; 1 = WC; 4 = WT; 5 = WP; and 6 = WB. Other values are reserved and cause EPT misconfigurations (see Section 25.2.3).
- If CR0.CD = 0, the effective memory type depends upon the value of bit 6 of the last EPT paging-structure entry:

- 
1. If the capability MSR IA32\_VMX\_CRO\_FIXED0 reports that CR0.PG must be 1 in VMX operation, CR0.PG can be 0 in VMX non-root operation only if the “unrestricted guest” VM-execution control and bit 31 of the primary processor-based VM-execution controls are both 1.
  2. Table 11-11 in Section 11.12.3, “Selecting a Memory Type from the PAT” illustrates how the PAT memory type is selected based on the values of the PAT, PCD, and PWT bits in a page-table entry (or page-directory entry with PS = 1). For accesses to a guest paging-structure entry X, the PAT memory type is selected from the table by using a value of 0 for the PAT bit with the values of PCD and PWT from the paging-structure entry Y that references X (or from CR3 if X is in the root paging structure). With PAE paging, the PAT memory type for accesses to the PDPTEs is WB.

## VMX SUPPORT FOR ADDRESS TRANSLATION

- If the value is 0, the effective memory type is the combination of the EPT memory type and the PAT memory type specified in Table 11-7 in Section 11.5.2.2, using the EPT memory type in place of the MTRR memory type.
- If the value is 1, the memory type used for the access is the EPT memory type. The PAT memory type is ignored.
- If CRO.CD = 1, the effective memory type is UC.

The MTRRs have no effect on the memory type used for an access to a guest-physical address.

## 25.3 CACHING TRANSLATION INFORMATION

Processors supporting Intel® 64 and IA-32 architectures may accelerate the address-translation process by caching on the processor data from the structures in memory that control that process. Such caching is discussed in Section 4.10, “Caching Translation Information” in the *Intel® 64 and IA-32 Architectures Software Developer’s Manual, Volume 3A*. The current section describes how this caching interacts with the VMX architecture.

The VPID and EPT features of the architecture for VMX operation augment this caching architecture. EPT defines the guest-physical address space and defines translations to that address space (from the linear-address space) and from that address space (to the physical-address space). Both features control the ways in which a logical processor may create and use information cached from the paging structures.

Section 25.3.1 describes the different kinds of information that may be cached. Section 25.3.2 specifies when such information may be cached and how it may be used. Section 25.3.3 details how software can invalidate cached information.

### 25.3.1 Information That May Be Cached

Section 4.10, “Caching Translation Information” in *Intel® 64 and IA-32 Architectures Software Developer’s Manual, Volume 3A* identifies two kinds of translation-related information that may be cached by a logical processor: **translations**, which are mappings from linear page numbers to physical page frames, and **paging-structure caches**, which map the upper bits of a linear page number to information from the paging-structure entries used to translate linear addresses matching those upper bits.

The same kinds of information may be cached when VPIDs and EPT are in use. A logical processor may cache and use such information based on its function. Information with different functionality is identified as follows:

- **Linear mappings.**<sup>1</sup> There are two kinds:

---

1. Earlier versions of this manual used the term “VPID-tagged” to identify linear mappings.

- Linear translations. Each of these is a mapping from a linear page number to the physical page frame to which it translates, along with information about access privileges and memory typing.
- Linear paging-structure-cache entries. Each of these is a mapping from the upper portion of a linear address to the physical address of the paging structure used to translate the corresponding region of the linear-address space, along with information about access privileges. For example, bits 47:39 of a linear address would map to the address of the relevant page-directory-pointer table.

Linear mappings do not contain information from any EPT paging structure.

- **Guest-physical mappings.**<sup>1</sup> There are two kinds:
  - Guest-physical translations. Each of these is a mapping from a guest-physical page number to the physical page frame to which it translates, along with information about access privileges and memory typing.
  - Guest-physical paging-structure-cache entries. Each of these is a mapping from the upper portion of a guest-physical address to the physical address of the EPT paging structure used to translate the corresponding region of the guest-physical address space, along with information about access privileges.

The information in guest-physical mappings about access privileges and memory typing is derived from EPT paging structures.

- **Combined mappings.**<sup>2</sup> There are two kinds:
  - Combined translations. Each of these is a mapping from a linear page number to the physical page frame to which it translates, along with information about access privileges and memory typing.
  - Combined paging-structure-cache entries. Each of these is a mapping from the upper portion of a linear address to the physical address of the paging structure used to translate the corresponding region of the linear-address space, along with information about access privileges.

The information in combined mappings about access privileges and memory typing is derived from both guest paging structures and EPT paging structures.

### 25.3.2 Creating and Using Cached Translation Information

The following items detail the creation of the mappings described in the previous section:<sup>3</sup>

- The following items describe the creation of mappings while EPT is not in use (including execution outside VMX non-root operation):

- 
1. Earlier versions of this manual used the term “EPTP-tagged” to identify guest-physical mappings.
  2. Earlier versions of this manual used the term “dual-tagged” to identify combined mappings.

## VMX SUPPORT FOR ADDRESS TRANSLATION

- Linear mappings may be created. They are derived from the paging structures referenced (directly or indirectly) by the current value of CR3 and are associated with the current VPID and the current PCID.
- No linear mappings are created with information derived from paging-structure entries that are not present (bit 0 is 0) or that set reserved bits. For example, if a PTE is not present, no linear mapping are created for any linear page number whose translation would use that PTE.
- No guest-physical or combined mappings are created while EPT is not in use.
- The following items describe the creation of mappings while EPT is in use:
  - Guest-physical mappings may be created. They are derived from the EPT paging structures referenced (directly or indirectly) by bits 51:12 of the current EPTP. These 40 bits contain the address of the EPT-PML4-table. (the notation **EP4TA** refers to those 40 bits). Newly created guest-physical mappings are associated with the current EP4TA.
  - Combined mappings may be created. They are derived from the EPT paging structures referenced (directly or indirectly) by the current EP4TA. If CRO.PG = 1, they are also derived from the paging structures referenced (directly or indirectly) by the current value of CR3. They are associated with the current VPID, the current PCID, and the current EP4TA.<sup>1</sup> No combined paging-structure-cache entries are created if CRO.PG = 0.<sup>2</sup>
  - No guest-physical mappings or combined mappings are created with information derived from EPT paging-structure entries that are not present (bits 2:0 are all 0) or that are misconfigured (see Section 25.2.3.1).
  - No combined mappings are created with information derived from guest paging-structure entries that are not present or that set reserved bits.
  - No linear mappings are created while EPT is in use.

The following items detail the use of the various mappings:

- If EPT is not in use (e.g., when outside VMX non-root operation), a logical processor may use cached mappings as follows:

- 
- 3. This section associated cached information with the current VPID and PCID. If PCIDs are not supported or are not being used (e.g., because CR4.PCIDE = 0), all the information is implicitly associated with PCID 000H; see Section 4.10.1, "Process-Context Identifiers (PCIDs)," in *Intel® 64 and IA-32 Architectures Software Developer's Manual, Volume 3A*.
  - 1. At any given time, a logical processor may be caching combined mappings for a VPID and a PCID that are associated with different EP4TAs. Similarly, it may be caching combined mappings for an EP4TA that are associated with different VPIIDs and PCIDs.
  - 2. If the capability MSR IA32\_VMX\_CRO\_FIXED0 reports that CRO.PG must be 1 in VMX operation, CRO.PG can be 0 in VMX non-root operation only if the "unrestricted guest" VM-execution control and bit 31 of the primary processor-based VM-execution controls are both 1.

- For accesses using linear addresses, it may use linear mappings associated with the current VPID and the current PCID. It may also use global TLB entries (linear mappings) associated with the current VPID and any PCID.
- No guest-physical or combined mappings are used while EPT is not in use.
- If EPT is in use, a logical processor may use cached mappings as follows:
  - For accesses using linear addresses, it may use combined mappings associated with the current VPID, the current PCID, and the current EP4TA. It may also use global TLB entries (combined mappings) associated with the current VPID, the current EP4TA, and any PCID.
  - For accesses using guest-physical addresses, it may use guest-physical mappings associated with the current EP4TA.
  - No linear mappings are used while EPT is in use.

### 25.3.3 Invalidating Cached Translation Information

Software modifications of paging structures (including EPT paging structures) may result in inconsistencies between those structures and the mappings cached by a logical processor. Certain operations invalidate information cached by a logical processor and can be used to eliminate such inconsistencies.

#### 25.3.3.1 Operations that Invalidate Cached Mappings

The following operations invalidate cached mappings as indicated:

- Operations that architecturally invalidate entries in the TLBs or paging-structure caches independent of VMX operation (e.g., the INVLPG instruction) invalidate linear mappings and combined mappings.<sup>1</sup> They are required to do so only for the current VPID (but, for combined mappings, all EP4TAs). Linear mappings for the current VPID are invalidated even if EPT is in use.<sup>2</sup> Combined mappings for the current VPID are invalidated even if EPT is not in use.<sup>3</sup>
- An EPT violation invalidates any guest-physical mappings (associated with the current EP4TA) that would be used to translate the guest-physical address that

- 
1. See Section 4.10.4, "Invalidation of TLBs and Paging-Structure Caches," in the *Intel® 64 and IA-32 Architectures Software Developer's Manual, Volume 3A* for an enumeration of operations that architecturally invalidate entries in the TLBs and paging-structure caches independent of VMX operation.
  2. While no linear mappings are created while EPT is in use, a logical processor may retain, while EPT is in use, linear mappings (for the same VPID as the current one) there were created earlier, when EPT was not in use.
  3. While no combined mappings are created while EPT is not in use, a logical processor may retain, while EPT is in not use, combined mappings (for the same VPID as the current one) there were created earlier, when EPT was in use.

## VMX SUPPORT FOR ADDRESS TRANSLATION

caused the EPT violation. If that guest-physical address was the translation of a linear address, the EPT violation also invalidates any combined mappings for that linear address associated with the current PCID, the current VPID and the current EP4TA.

- If the “enable VPID” VM-execution control is 0, VM entries and VM exits invalidate linear mappings and combined mappings associated with VPID 0000H (for all PCIDs). Combined mappings for VPID 0000H are invalidated for all EP4TAs.
- Execution of the INVVPID instruction invalidates linear mappings and combined mappings. Invalidation is based on instruction operands, called the INVVPID type and the INVVPID descriptor. Four INVVPID types are currently defined:
  - **Individual-address.** If the INVVPID type is 0, the logical processor invalidates linear mappings and combined mappings associated with the VPID specified in the INVVPID descriptor and that would be used to translate the linear address specified in of the INVVPID descriptor. Linear mappings and combined mappings for that VPID and linear address are invalidated for all PCIDs and, for combined mappings, all EP4TAs. (The instruction may also invalidate mappings associated with other VPIDs and for other linear addresses.)
  - **Single-context.** If the INVVPID type is 1, the logical processor invalidates all linear mappings and combined mappings associated with the VPID specified in the INVVPID descriptor. Linear mappings and combined mappings for that VPID are invalidated for all PCIDs and, for combined mappings, all EP4TAs. (The instruction may also invalidate mappings associated with other VPIDs.)
  - **All-context.** If the INVVPID type is 2, the logical processor invalidates linear mappings and combined mappings associated with all VPIDs except VPID 0000H and with all PCIDs. (In some cases, it may invalidate linear mappings with VPID 0000H as well.) Combined mappings are invalidated for all EP4TAs.
  - **Single-context-retaining-globals.** If the INVVPID type is 3, the logical processor invalidates linear mappings and combined mappings associated with the VPID specified in the INVVPID descriptor. Linear mappings and combined mappings for that VPID are invalidated for all PCIDs and, for combined mappings, all EP4TAs. The logical processor is **not** required to invalidate information that was used for **global** translations (although it may do so). See Section 4.10, “Caching Translation Information” for details regarding global translations. (The instruction may invalidate mappings associated with other VPIDs.)

See Chapter 5 of the *Intel® 64 and IA-32 Architectures Software Developer’s Manual, Volume 2B* for details of the INVVPID instruction. See Section 25.3.3.3 for guidelines regarding use of this instruction.

- Execution of the INVEPT instruction invalidates guest-physical mappings and combined mappings. Invalidation is based on instruction operands, called the INVEPT type and the INVEPT descriptor. Two INVEPT types are currently defined:

- **Single-context.** If the INVEPT type is 1, the logical processor invalidates all guest-physical mappings and combined mappings associated with the EP4TA specified in the INVEPT descriptor. Combined mappings for that EP4TA are invalidated for all VPIDs and all PCIDs. (The instruction may invalidate mappings associated with other EP4TAs.)
- **All-context.** If the INVEPT type is 2, the logical processor invalidates guest-physical mappings and combined mappings associated with all EP4TAs (and, for combined mappings, for all VPIDs and PCIDs).

See Chapter 5 of the *Intel® 64 and IA-32 Architectures Software Developer’s Manual, Volume 2B* for details of the INVEPT instruction. See Section 25.3.3.4 for guidelines regarding use of this instruction.

- A power-up or a reset invalidates all linear mappings, guest-physical mappings, and combined mappings.

### 25.3.3.2 Operations that Need Not Invalidate Cached Mappings

The following items detail cases of operations that are not required to invalidate certain cached mappings:

- Operations that architecturally invalidate entries in the TLBs or paging-structure caches independent of VMX operation are not required to invalidate any guest-physical mappings.
- The INVVPID instruction is not required to invalidate any guest-physical mappings.
- The INVEPT instruction is not required to invalidate any linear mappings.
- VMX transitions are not required to invalidate any guest-physical mappings. If the “enable VPID” VM-execution control is 1, VMX transitions are not required to invalidate any linear mappings or combined mappings.
- The VMXOFF and VMXON instructions are not required to invalidate any linear mappings, guest-physical mappings, or combined mappings.

A logical processor may invalidate any cached mappings at any time. For this reason, the operations identified above may invalidate the indicated mappings despite the fact that doing so is not required.

### 25.3.3.3 Guidelines for Use of the INVVPID Instruction

The need for VMM software to use the INVVPID instruction depends on how that software is virtualizing memory (e.g., see Section 28.3, “Memory Virtualization”).

If EPT is not in use, it is likely that the VMM is virtualizing the guest paging structures. Such a VMM may configure the VMCS so that all or some of the operations that invalidate entries in the TLBs and the paging-structure caches (e.g., the INVLPG instruction) cause VM exits. If VMM software is emulating these operations, it may be necessary to use the INVVPID instruction to ensure that the logical processor’s TLBs and the paging-structure caches are appropriately invalidated.

## VMX SUPPORT FOR ADDRESS TRANSLATION

Requirements of when software should use the INVVPID instruction depend on the specific algorithm being used for page-table virtualization. The following items provide guidelines for software developers:

- Emulation of the INVLPG instruction may require execution of the INVVPID instruction as follows:
  - The INVVPID type is individual-address (0).
  - The VPID in the INVVPID descriptor is the one assigned to the virtual processor whose execution is being emulated.
  - The linear address in the INVVPID descriptor is that of the operand of the INVLPG instruction being emulated.
- Some instructions invalidate all entries in the TLBs and paging-structure caches—except for global translations. An example is the MOV to CR3 instruction. (See Section 4.10, “Caching Translation Information” in the *Intel® 64 and IA-32 Architectures Software Developer’s Manual, Volume 3A* for details regarding global translations.) Emulation of such an instruction may require execution of the INVVPID instruction as follows:
  - The INVVPID type is single-context-retaining-globals (3).
  - The VPID in the INVVPID descriptor is the one assigned to the virtual processor whose execution is being emulated.
- Some instructions invalidate all entries in the TLBs and paging-structure caches—including for global translations. An example is the MOV to CR4 instruction if the value of value of bit 4 (page global enable—PGE) is changing. Emulation of such an instruction may require execution of the INVVPID instruction as follows:
  - The INVVPID type is single-context (1).
  - The VPID in the INVVPID descriptor is the one assigned to the virtual processor whose execution is being emulated.

If EPT is not in use, the logical processor associates all mappings it creates with the current VPID, and it will use such mappings to translate linear addresses. For that reason, a VMM should not use the same VPID for different non-EPT guests that use different page tables. Doing so may result in one guest using translations that pertain to the other.

If EPT is in use, the instructions enumerated above might not be configured to cause VM exits and the VMM might not be emulating them. In that case, executions of the instructions by guest software properly invalidate the required entries in the TLBs and paging-structure caches (see Section 25.3.3.1); execution of the INVVPID instruction is not required.

If EPT is in use, the logical processor associates all mappings it creates with the value of bits 51:12 of current EPTP. If a VMM uses different EPTP values for different guests, it may use the same VPID for those guests. Doing so cannot result in one guest using translations that pertain to the other.

The following guidelines apply more generally and are appropriate even if EPT is in use:

- As detailed in Section 22.2.1.1, an access to the APIC-access page might not cause an APIC-access VM exit if software does not properly invalidate information that may be cached from the paging structures. If, at one time, the current VPID on a logical processor was a non-zero value X, it is recommended that software use the INVVPID instruction with the “single-context” INVVPID type and with VPID X in the INVVPID descriptor before a VM entry on the same logical processor that establishes VPID X and either (a) the “virtualize APIC accesses” VM-execution control was changed from 0 to 1; or (b) the value of the APIC-access address was changed.
- Software can use the INVVPID instruction with the “all-context” INVVPID type immediately after execution of the VMXON instruction or immediately prior to execution of the VMXOFF instruction. Either prevents potentially undesired retention of information cached from paging structures between separate uses of VMX operation.

#### 25.3.3.4 Guidelines for Use of the INVEPT Instruction

The following items provide guidelines for use of the INVEPT instruction to invalidate information cached from the EPT paging structures.

- Software should use the INVEPT instruction with the “single-context” INVEPT type after making any of the following changes to an EPT paging-structure entry (the INVEPT descriptor should contain an EPTP value that references — directly or indirectly — the modified EPT paging structure):
  - Changing any of the privilege bits 2:0 from 1 to 0.
  - Changing the physical address in bits 51:12.
  - For an EPT PDPTE or an EPT PDE, changing bit 7 (which determines whether the entry maps a page).
  - For the **last** EPT paging-structure entry used to translate a guest-physical address (either an EPT PDE with bit 7 set to 1 or an EPT PTE), changing either bits 5:3 or bit 6. (These bits determine the effective memory type of accesses using that EPT paging-structure entry; see Section 25.2.4.)
- Software may use the INVEPT instruction after modifying a present EPT paging-structure entry to change any of the privilege bits 2:0 from 0 to 1. Failure to do so may cause an EPT violation that would not otherwise occur. Because an EPT violation invalidates any mappings that would be used by the access that caused the EPT violation (see Section 25.3.3.1), an EPT violation will not recur if the original access is performed again, even if the INVEPT instruction is not executed.
- Because a logical processor does not cache any information derived from EPT paging-structure entries that are not present or misconfigured (see Section 25.2.3.1), it is not necessary to execute INVEPT following modification of an EPT paging-structure entry that had been not present or misconfigured.

## VMX SUPPORT FOR ADDRESS TRANSLATION

- As detailed in Section 22.2.1.1 and Section 22.2.2.1, an access to the APIC-access page might not cause an APIC-access VM exit if software does not properly invalidate information that may be cached from the EPT paging structures. If EPT was in use on a logical processor at one time with EPTP X, it is recommended that software use the INVEPT instruction with the “single-context” INVEPT type and with EPTP X in the INVEPT descriptor before a VM entry on the same logical processor that enables EPT with EPTP X and either (a) the “virtualize APIC accesses” VM-execution control was changed from 0 to 1; or (b) the value of the APIC-access address was changed.
- Software can use the INVEPT instruction with the “all-context” INVEPT type immediately after execution of the VMXON instruction or immediately prior to execution of the VMXOFF instruction. Either prevents potentially undesired retention of information cached from EPT paging structures between separate uses of VMX operation.

In a system containing more than one logical processor, software must account for the fact that information from an EPT paging-structure entry may be cached on logical processors other than the one that modifies that entry. The process of propagating the changes to a paging-structure entry is commonly referred to as “TLB shootdown.” A discussion of TLB shootdown appears in Section 4.10.5, “Propagation of Paging-Structure Changes to Multiple Processors,” in the *Intel® 64 and IA-32 Architectures Software Developer’s Manual, Volume 3A*.

# CHAPTER 26

## SYSTEM MANAGEMENT MODE

---

This chapter describes aspects of IA-64 and IA-32 architecture used in system management mode (SMM).

SMM provides an alternate operating environment that can be used to monitor and manage various system resources for more efficient energy usage, to control system hardware, and/or to run proprietary code. It was introduced into the IA-32 architecture in the Intel386 SL processor (a mobile specialized version of the Intel386 processor). It is also available in the Pentium M, Pentium 4, Intel Xeon, P6 family, and Pentium and Intel486 processors (beginning with the enhanced versions of the Intel486 SL and Intel486 processors).

### 26.1 SYSTEM MANAGEMENT MODE OVERVIEW

SMM is a special-purpose operating mode provided for handling system-wide functions like power management, system hardware control, or proprietary OEM-designed code. It is intended for use only by system firmware, not by applications software or general-purpose systems software. The main benefit of SMM is that it offers a distinct and easily isolated processor environment that operates transparently to the operating system or executive and software applications.

When SMM is invoked through a system management interrupt (SMI), the processor saves the current state of the processor (the processor's context), then switches to a separate operating environment contained in system management RAM (SMRAM). While in SMM, the processor executes SMI handler code to perform operations such as powering down unused disk drives or monitors, executing proprietary code, or placing the whole system in a suspended state. When the SMI handler has completed its operations, it executes a resume (RSM) instruction. This instruction causes the processor to reload the saved context of the processor, switch back to protected or real mode, and resume executing the interrupted application or operating-system program or task.

The following SMM mechanisms make it transparent to applications programs and operating systems:

- The only way to enter SMM is by means of an SMI.
- The processor executes SMM code in a separate address space (SMRAM) that can be made inaccessible from the other operating modes.
- Upon entering SMM, the processor saves the context of the interrupted program or task.

## SYSTEM MANAGEMENT MODE

- All interrupts normally handled by the operating system are disabled upon entry into SMM.
- The RSM instruction can be executed only in SMM.

SMM is similar to real-address mode in that there are no privilege levels or address mapping. An SMM program can address up to 4 GBytes of memory and can execute all I/O and applicable system instructions. See Section 26.5 for more information about the SMM execution environment.

### NOTES

Software developers should be aware that, even if a logical processor was using the physical-address extension (PAE) mechanism (introduced in the P6 family processors) or was in IA-32e mode before an SMI, this will not be the case after the SMI is delivered. This is because delivery of an SMI disables paging (see Table 26-4). (This does not apply if the dual-monitor treatment of SMIs and SMM is active; see Section 26.15.)

### 26.1.1 System Management Mode and VMX Operation

Traditionally, SMM services system management interrupts and then resumes program execution (back to the software stack consisting of executive and application software; see Section 26.2 through Section 26.13).

A virtual machine monitor (VMM) using VMX can act as a host to multiple virtual machines and each virtual machine can support its own software stack of executive and application software. On processors that support VMX, virtual-machine extensions may use system-management interrupts (SMIs) and system-management mode (SMM) in one of two ways:

- **Default treatment.** System firmware handles SMIs. The processor saves architectural states and critical states relevant to VMX operation upon entering SMM. When the firmware completes servicing SMIs, it uses RSM to resume VMX operation.
- **Dual-monitor treatment.** Two VM monitors collaborate to control the servicing of SMIs: one VMM operates outside of SMM to provide basic virtualization in support for guests; the other VMM operates inside SMM (while in VMX operation) to support system-management functions. The former is referred to as **executive monitor**, the latter **SMM monitor**.<sup>1</sup>

The default treatment is described in Section 26.14, “Default Treatment of SMIs and SMM with VMX Operation and SMX Operation”. Dual-monitor treatment of SMM is described in Section 26.15, “Dual-Monitor Treatment of SMIs and SMM”.

---

1. The dual-monitor treatment may not be supported by all processors. Software should consult the VMX capability MSR IA32\_VMX\_BASIC (see Appendix G.1) to determine whether it is supported.

## 26.2 SYSTEM MANAGEMENT INTERRUPT (SMI)

The only way to enter SMM is by signaling an SMI through the SMI# pin on the processor or through an SMI message received through the APIC bus. The SMI is a nonmaskable external interrupt that operates independently from the processor's interrupt- and exception-handling mechanism and the local APIC. The SMI takes precedence over an NMI and a maskable interrupt. SMM is non-reentrant; that is, the SMI is disabled while the processor is in SMM.

### NOTES

In the Pentium 4, Intel Xeon, and P6 family processors, when a processor that is designated as an application processor during an MP initialization sequence is waiting for a startup IPI (SIPI), it is in a mode where SMIs are masked. However if a SMI is received while an application processor is in the wait for SIPI mode, the SMI will be pended. The processor then responds on receipt of a SIPI by immediately servicing the pended SMI and going into SMM before handling the SIPI.

An SMI may be blocked for one instruction following execution of STI, MOV to SS, or POP into SS.

## 26.3 SWITCHING BETWEEN SMM AND THE OTHER PROCESSOR OPERATING MODES

Figure 2-3 shows how the processor moves between SMM and the other processor operating modes (protected, real-address, and virtual-8086). Signaling an SMI while the processor is in real-address, protected, or virtual-8086 modes always causes the processor to switch to SMM. Upon execution of the RSM instruction, the processor always returns to the mode it was in when the SMI occurred.

### 26.3.1 Entering SMM

The processor always handles an SMI on an architecturally defined "interruptible" point in program execution (which is commonly at an IA-32 architecture instruction boundary). When the processor receives an SMI, it waits for all instructions to retire and for all stores to complete. The processor then saves its current context in SMRAM (see Section 26.4), enters SMM, and begins to execute the SMI handler.

Upon entering SMM, the processor signals external hardware that SMM handling has begun. The signaling mechanism used is implementation dependent. For the P6 family processors, an SMI acknowledge transaction is generated on the system bus and the multiplexed status signal EXF4 is asserted each time a bus transaction is generated while the processor is in SMM. For the Pentium and Intel486 processors, the SMIACK# pin is asserted.

## SYSTEM MANAGEMENT MODE

An SMI has a greater priority than debug exceptions and external interrupts. Thus, if an NMI, maskable hardware interrupt, or a debug exception occurs at an instruction boundary along with an SMI, only the SMI is handled. Subsequent SMI requests are not acknowledged while the processor is in SMM. The first SMI interrupt request that occurs while the processor is in SMM (that is, after SMM has been acknowledged to external hardware) is latched and serviced when the processor exits SMM with the RSM instruction. The processor will latch only one SMI while in SMM.

See Section 26.5 for a detailed description of the execution environment when in SMM.

### 26.3.2 Exiting From SMM

The only way to exit SMM is to execute the RSM instruction. The RSM instruction is only available to the SMI handler; if the processor is not in SMM, attempts to execute the RSM instruction result in an invalid-opcode exception (#UD) being generated.

The RSM instruction restores the processor's context by loading the state save image from SMRAM back into the processor's registers. The processor then returns an SMIACK transaction on the system bus and returns program control back to the interrupted program.

Upon successful completion of the RSM instruction, the processor signals external hardware that SMM has been exited. For the P6 family processors, an SMI acknowledge transaction is generated on the system bus and the multiplexed status signal EXF4 is no longer generated on bus cycles. For the Pentium and Intel486 processors, the SMIACK# pin is deserted.

If the processor detects invalid state information saved in the SMRAM, it enters the shutdown state and generates a special bus cycle to indicate it has entered shutdown state. Shutdown happens only in the following situations:

- A reserved bit in control register CR4 is set to 1 on a write to CR4. This error should not happen unless SMI handler code modifies reserved areas of the SMRAM saved state map (see Section 26.4.1). CR4 is saved in the state map in a reserved location and cannot be read or modified in its saved state.
- An illegal combination of bits is written to control register CR0, in particular PG set to 1 and PE set to 0, or NW set to 1 and CD set to 0.
- CR4.PCIDE would be set to 1 and IA32\_EFER.LMA to 0.
- (For the Pentium and Intel486 processors only.) If the address stored in the SMBASE register when an RSM instruction is executed is not aligned on a 32-KByte boundary. This restriction does not apply to the P6 family processors.

In the shutdown state, Intel processors stop executing instructions until a RESET#, INIT# or NMI# is asserted. While Pentium family processors recognize the SMI# signal in shutdown state, P6 family and Intel486 processors do not. Intel does not support using SMI# to recover from shutdown states for any processor family; the response of processors in this circumstance is not well defined. On Pentium 4 and later processors, shutdown will inhibit INTR and A20M but will not change any of the

other inhibits. On these processors, NMIs will be inhibited if no action is taken in the SMM handler to uninhibit them (see Section 26.8).

If the processor is in the HALT state when the SMI is received, the processor handles the return from SMM slightly differently (see Section 26.10). Also, the SMBASE address can be changed on a return from SMM (see Section 26.11).

## 26.4 SMRAM

While in SMM, the processor executes code and stores data in the SMRAM space. The SMRAM space is mapped to the physical address space of the processor and can be up to 4 GBytes in size. The processor uses this space to save the context of the processor and to store the SMI handler code, data and stack. It can also be used to store system management information (such as the system configuration and specific information about powered-down devices) and OEM-specific information.

The default SMRAM size is 64 KBytes beginning at a base physical address in physical memory called the SMBASE (see Figure 26-1). The SMBASE default value following a hardware reset is 30000H. The processor looks for the first instruction of the SMI handler at the address [SMBASE + 8000H]. It stores the processor's state in the area from [SMBASE + FEOOH] to [SMBASE + FFFFH]. See Section 26.4.1 for a description of the mapping of the state save area.

The system logic is minimally required to decode the physical address range for the SMRAM from [SMBASE + 8000H] to [SMBASE + FFFFH]. A larger area can be decoded if needed. The size of this SMRAM can be between 32 KBytes and 4 GBytes.

The location of the SMRAM can be changed by changing the SMBASE value (see Section 26.11). It should be noted that all processors in a multiple-processor system are initialized with the same SMBASE value (30000H). Initialization software must sequentially place each processor in SMM and change its SMBASE so that it does not overlap those of other processors.

The actual physical location of the SMRAM can be in system memory or in a separate RAM memory. The processor generates an SMI acknowledge transaction (P6 family processors) or asserts the SMIACT# pin (Pentium and Intel486 processors) when the processor receives an SMI (see Section 26.3.1).

System logic can use the SMI acknowledge transaction or the assertion of the SMIACT# pin to decode accesses to the SMRAM and redirect them (if desired) to specific SMRAM memory. If a separate RAM memory is used for SMRAM, system logic should provide a programmable method of mapping the SMRAM into system memory space when the processor is not in SMM. This mechanism will enable start-up procedures to initialize the SMRAM space (that is, load the SMI handler) before executing the SMI handler during SMM.

## SYSTEM MANAGEMENT MODE

### 26.4.1 SMRAM State Save Map

When an IA-32 processor that does not support Intel 64 architecture initially enters SMM, it writes its state to the state save area of the SMRAM. The state save area begins at [SMBASE + 8000H + 7FFFH] and extends down to [SMBASE + 8000H + 7E00H]. Table 26-1 shows the state save map. The offset in column 1 is relative to the SMBASE value plus 8000H. Reserved spaces should not be used by software.

Some of the registers in the SMRAM state save area (marked YES in column 3) may be read and changed by the SMI handler, with the changed values restored to the processor registers by the RSM instruction. Some register images are read-only, and must not be modified (modifying these registers will result in unpredictable behavior). An SMI handler should not rely on any values stored in an area that is marked as reserved.

Figure 26-1. SMRAM Usage

Table 26-1. SMRAM State Save Map

| Offset<br>(Added to SMBASE +<br>8000H) | Register | Writable? |
|----------------------------------------|----------|-----------|
| 7FFCH                                  | CRO      | No        |
| 7FF8H                                  | CR3      | No        |
| 7FF4H                                  | EFLAGS   | Yes       |
| 7FF0H                                  | EIP      | Yes       |
| 7FECH                                  | EDI      | Yes       |
| 7FE8H                                  | ESI      | Yes       |
| 7FE4H                                  | EBP      | Yes       |
| 7FE0H                                  | ESP      | Yes       |

Table 26-1. SMRAM State Save Map (Contd.)

| Offset<br>(Added to SMBASE +<br>8000H) | Register                                   | Writable? |
|----------------------------------------|--------------------------------------------|-----------|
| 7FDCH                                  | EBX                                        | Yes       |
| 7FD8H                                  | EDX                                        | Yes       |
| 7FD4H                                  | ECX                                        | Yes       |
| 7FD0H                                  | EAX                                        | Yes       |
| 7FCCH                                  | DR6                                        | No        |
| 7FC8H                                  | DR7                                        | No        |
| 7FC4H                                  | TR <sup>1</sup>                            | No        |
| 7FC0H                                  | Reserved                                   | No        |
| 7FBCH                                  | GS <sup>1</sup>                            | No        |
| 7FB8H                                  | FS <sup>1</sup>                            | No        |
| 7FB4H                                  | DS <sup>1</sup>                            | No        |
| 7FB0H                                  | SS <sup>1</sup>                            | No        |
| 7FACH                                  | CS <sup>1</sup>                            | No        |
| 7FA8H                                  | ES <sup>1</sup>                            | No        |
| 7FA4H                                  | I/O State Field, see Section 26.7          | No        |
| 7FA0H                                  | I/O Memory Address Field, see Section 26.7 | No        |
| 7F9FH-7F03H                            | Reserved                                   | No        |
| 7F02H                                  | Auto HALT Restart Field (Word)             | Yes       |
| 7FO0H                                  | I/O Instruction Restart Field (Word)       | Yes       |
| 7EFCH                                  | SMM Revision Identifier Field (Doubleword) | No        |
| 7EF8H                                  | SMBASE Field (Doubleword)                  | Yes       |
| 7EF7H - 7EOOH                          | Reserved                                   | No        |

**NOTE:**

1. The two most significant bytes are reserved.

The following registers are saved (but not readable) and restored upon exiting SMM:

- Control register CR4. (This register is cleared to all 0s when entering SMM).
- The hidden segment descriptor information stored in segment registers CS, DS, ES, FS, GS, and SS.

## SYSTEM MANAGEMENT MODE

If an SMI request is issued for the purpose of powering down the processor, the values of all reserved locations in the SMM state save must be saved to nonvolatile memory.

The following state is not automatically saved and restored following an SMI and the RSM instruction, respectively:

- Debug registers DR0 through DR3.
- The x87 FPU registers.
- The MTRRs.
- Control register CR2.
- The model-specific registers (for the P6 family and Pentium processors) or test registers TR3 through TR7 (for the Pentium and Intel486 processors).
- The state of the trap controller.
- The machine-check architecture registers.
- The APIC internal interrupt state (ISR, IRR, etc.).
- The microcode update state.

If an SMI is used to power down the processor, a power-on reset will be required before returning to SMM, which will reset much of this state back to its default values. So an SMI handler that is going to trigger power down should first read these registers listed above directly, and save them (along with the rest of RAM) to nonvolatile storage. After the power-on reset, the continuation of the SMI handler should restore these values, along with the rest of the system's state. Anytime the SMI handler changes these registers in the processor, it must also save and restore them.

### NOTES

A small subset of the MSRs (such as, the time-stamp counter and performance-monitoring counters) are not arbitrarily writable and therefore cannot be saved and restored. SMM-based power-down and restoration should only be performed with operating systems that do not use or rely on the values of these registers.

Operating system developers should be aware of this fact and insure that their operating-system assisted power-down and restoration software is immune to unexpected changes in these register values.

#### 26.4.1.1 SMRAM State Save Map and Intel 64 Architecture

When the processor initially enters SMM, it writes its state to the state save area of the SMRAM. The state save area on an Intel 64 processor at [SMBASE + 8000H + 7FFFH] and extends to [SMBASE + 8000H + 7C00H].

Support for Intel 64 architecture is reported by CPUID.80000001:EDX[29] = 1. The layout of the SMRAM state save map is shown in Table 26-3.

Additionally, the SMRAM state save map shown in Table 26-3 also applies to processors with the following CPUID signatures listed in Table 26-2, irrespective of the value in CPUID.80000001:EDX[29].

**Table 26-2. Processor Signatures and 64-bit SMRAM State Save Map Format**

| DisplayFamily_DisplayModel | Processor Families/Processor Number Series                                                                                                                         |
|----------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 06_17H                     | Intel Xeon Processor 5200, 5400 series, Intel Core 2 Quad processor Q9xxx, Intel Core 2 Duo processors E8000, T9000,                                               |
| 06_0FH                     | Intel Xeon Processor 3000, 3200, 5100, 5300, 7300 series, Intel Core 2 Quad, Intel Core 2 Extreme, Intel Core 2 Duo processors, Intel Pentium dual-core processors |
| 06_1CH                     | Intel® Atom™ processors                                                                                                                                            |

**Table 26-3. SMRAM State Save Map for Intel 64 Architecture**

| Offset<br>(Added to SMBASE +<br>8000H) | Register              | Writable? |
|----------------------------------------|-----------------------|-----------|
| 7FF8H                                  | CRO                   | No        |
| 7FF0H                                  | CR3                   | No        |
| 7FE8H                                  | RFLAGS                | Yes       |
| 7FE0H                                  | IA32_EFER             | Yes       |
| 7FD8H                                  | RIP                   | Yes       |

| 7DD0H                                  | GDT Base (Upper 32 bits) | No        |
| 7DCFH - 7C00H                          | Reserved                 | No        |

**NOTE:**

1. The two most significant bytes are reserved.

#### 26.4.2 SMRAM Caching

An IA-32 processor does not automatically write back and invalidate its caches before entering SMM or before exiting SMM. Because of this behavior, care must be taken in the placement of the SMRAM in system memory and in the caching of the SMRAM to prevent cache incoherence when switching back and forth between SMM and protected mode operation. Either of the following three methods of locating the SMRAM in system memory will guarantee cache coherency:

- Place the SRAM in a dedicated section of system memory that the operating system and applications are prevented from accessing. Here, the SRAM can be designated as cacheable (WB, WT, or WC) for optimum processor performance, without risking cache incoherence when entering or exiting SMM.
- Place the SRAM in a section of memory that overlaps an area used by the operating system (such as the video memory), but designate the SMRAM as uncacheable (UC). This method prevents cache access when in SMM to maintain cache coherency, but the use of uncacheable memory reduces the performance of SMM code.
- Place the SRAM in a section of system memory that overlaps an area used by the operating system and/or application code, but explicitly flush (write back and invalidate) the caches upon entering and exiting SMM mode. This method maintains cache coherency, but the incurs the overhead of two complete cache flushes.

## SYSTEM MANAGEMENT MODE

For Pentium 4, Intel Xeon, and P6 family processors, a combination of the first two methods of locating the SMRAM is recommended. Here the SMRAM is split between an overlapping and a dedicated region of memory. Upon entering SMM, the SMRAM space that is accessed overlaps video memory (typically located in low memory). This SMRAM section is designated as UC memory. The initial SMM code then jumps to a second SMRAM section that is located in a dedicated region of system memory (typically in high memory). This SMRAM section can be cached for optimum processor performance.

For systems that explicitly flush the caches upon entering SMM (the third method described above), the cache flush can be accomplished by asserting the FLUSH# pin at the same time as the request to enter SMM (generally initiated by asserting the SMI# pin). The priorities of the FLUSH# and SMI# pins are such that the FLUSH# is serviced first. To guarantee this behavior, the processor requires that the following constraints on the interaction of FLUSH# and SMI# be met. In a system where the FLUSH# and SMI# pins are synchronous and the set up and hold times are met, then the FLUSH# and SMI# pins may be asserted in the same clock. In asynchronous systems, the FLUSH# pin must be asserted at least one clock before the SMI# pin to guarantee that the FLUSH# pin is serviced first.

Upon leaving SMM (for systems that explicitly flush the caches), the WBINVD instruction should be executed prior to leaving SMM to flush the caches.

### NOTES

In systems based on the Pentium processor that use the FLUSH# pin to write back and invalidate cache contents before entering SMM, the processor will prefetch at least one cache line in between when the Flush Acknowledge cycle is run and the subsequent recognition of SMI# and the assertion of SMIACK#.

It is the obligation of the system to ensure that these lines are not cached by returning KEN# inactive to the Pentium processor.

#### 26.4.2.1 System Management Range Registers (SMRR)

SMI handler code and data stored by SMM code resides in SMRAM. The SMRR interface is an enhancement in Intel 64 architecture to limit cacheable reference of addresses in SMRAM to code running in SMM. The SMRR interface can be configured only by code running in SMM. Details of SMRR is described in Section 11.11.2.4.

## 26.5 SMI HANDLER EXECUTION ENVIRONMENT

After saving the current context of the processor, the processor initializes its core registers to the values shown in Table 26-4. Upon entering SMM, the PE and PG flags in control register C0 are cleared, which places the processor in an environment similar to real-address mode. The differences between the SMM execution environment and the real-address mode execution environment are as follows:

- The addressable SMRAM address space ranges from 0 to FFFFFFFFH (4 GBytes). (The physical address extension — enabled with the PAE flag in control register CR4 — is not supported in SMM.)
- The normal 64-KByte segment limit for real-address mode is increased to 4 GBytes.
- The default operand and address sizes are set to 16 bits, which restricts the addressable SMRAM address space to the 1-MByte real-address mode limit for native real-address-mode code. However, operand-size and address-size override prefixes can be used to access the address space beyond the 1-MByte.

Table 26-4. Processor Register Initialization in SMM

| Register                     | Contents                                             |
|------------------------------|------------------------------------------------------|
| General-purpose registers    | Undefined                                            |
| EFLAGS                       | 00000002H                                            |
| EIP                          | 00008000H                                            |
| CS selector                  | SMM Base shifted right 4 bits (default 3000H)        |
| CS base                      | SMM Base (default 3000H)                             |
| DS, ES, FS, GS, SS Selectors | 0000H                                                |
| DS, ES, FS, GS, SS Bases     | 00000000H                                            |
| DS, ES, FS, GS, SS Limits    | 0FFFFFFFH                                            |
| CR0                          | PE, EM, TS, and PG flags set to 0; others unmodified |
| CR4                          | Cleared to zero                                      |
| DR6                          | Undefined                                            |
| DR7                          | 00000400H                                            |

- Near jumps and calls can be made to anywhere in the 4-GByte address space if a 32-bit operand-size override prefix is used. Due to the real-address-mode style of base-address formation, a far call or jump cannot transfer control to a segment with a base address of more than 20 bits (1 MByte). However, since the segment limit in SMM is 4 GBytes, offsets into a segment that go beyond the 1-MByte limit are allowed when using 32-bit operand-size override prefixes. Any program control transfer that does not have a 32-bit operand-size override prefix truncates the EIP value to the 16 low-order bits.
- Data and the stack can be located anywhere in the 4-GByte address space, but can be accessed only with a 32-bit address-size override if they are located above 1 MByte. As with the code segment, the base address for a data or stack segment cannot be more than 20 bits.

The value in segment register CS is automatically set to the default of 3000H for the SMBASE shifted 4 bits to the right; that is, 3000H. The EIP register is set to 8000H. When the EIP value is added to shifted CS value (the SMBASE), the resulting linear address points to the first instruction of the SMI handler.

## SYSTEM MANAGEMENT MODE

The other segment registers (DS, SS, ES, FS, and GS) are cleared to 0 and their segment limits are set to 4 GBytes. In this state, the SMRAM address space may be treated as a single flat 4-GByte linear address space. If a segment register is loaded with a 16-bit value, that value is then shifted left by 4 bits and loaded into the segment base (hidden part of the segment register). The limits and attributes are not modified.

Maskable hardware interrupts, exceptions, NMI interrupts, SMI interrupts, A20M interrupts, single-step traps, breakpoint traps, and INIT operations are inhibited when the processor enters SMM. Maskable hardware interrupts, exceptions, single-step traps, and breakpoint traps can be enabled in SMM if the SMM execution environment provides and initializes an interrupt table and the necessary interrupt and exception handlers (see Section 26.6).

## 26.6 EXCEPTIONS AND INTERRUPTS WITHIN SMM

When the processor enters SMM, all hardware interrupts are disabled in the following manner:

- The IF flag in the EFLAGS register is cleared, which inhibits maskable hardware interrupts from being generated.
- The TF flag in the EFLAGS register is cleared, which disables single-step traps.
- Debug register DR7 is cleared, which disables breakpoint traps. (This action prevents a debugger from accidentally breaking into an SMM handler if a debug breakpoint is set in normal address space that overlays code or data in SMRAM.)
- NMI, SMI, and A20M interrupts are blocked by internal SMM logic. (See Section 26.8 for more information about how NMIs are handled in SMM.)

Software-invoked interrupts and exceptions can still occur, and maskable hardware interrupts can be enabled by setting the IF flag. Intel recommends that SMM code be written in so that it does not invoke software interrupts (with the INT *n*, INTO, INT 3, or BOUND instructions) or generate exceptions.

If the SMM handler requires interrupt and exception handling, an SMM interrupt table and the necessary exception and interrupt handlers must be created and initialized from within SMM. Until the interrupt table is correctly initialized (using the LIDT instruction), exceptions and software interrupts will result in unpredictable processor behavior.

The following restrictions apply when designing SMM interrupt and exception-handling facilities:

- The interrupt table should be located at linear address 0 and must contain real-address mode style interrupt vectors (4 bytes containing CS and IP).
- Due to the real-address mode style of base address formation, an interrupt or exception cannot transfer control to a segment with a base address of more than 20 bits.

- An interrupt or exception cannot transfer control to a segment offset of more than 16 bits (64 KBytes).
- When an exception or interrupt occurs, only the 16 least-significant bits of the return address (EIP) are pushed onto the stack. If the offset of the interrupted procedure is greater than 64 KBytes, it is not possible for the interrupt/exception handler to return control to that procedure. (One solution to this problem is for a handler to adjust the return address on the stack.)
- The SMBASE relocation feature affects the way the processor will return from an interrupt or exception generated while the SMI handler is executing. For example, if the SMBASE is relocated to above 1 MByte, but the exception handlers are below 1 MByte, a normal return to the SMI handler is not possible. One solution is to provide the exception handler with a mechanism for calculating a return address above 1 MByte from the 16-bit return address on the stack, then use a 32-bit far call to return to the interrupted procedure.
- If an SMI handler needs access to the debug trap facilities, it must insure that an SMM accessible debug handler is available and save the current contents of debug registers DR0 through DR3 (for later restoration). Debug registers DR0 through DR3 and DR7 must then be initialized with the appropriate values.
- If an SMI handler needs access to the single-step mechanism, it must insure that an SMM accessible single-step handler is available, and then set the TF flag in the EFLAGS register.
- If the SMI design requires the processor to respond to maskable hardware interrupts or software-generated interrupts while in SMM, it must ensure that SMM accessible interrupt handlers are available and then set the IF flag in the EFLAGS register (using the STI instruction). Software interrupts are not blocked upon entry to SMM, so they do not need to be enabled.

## 26.7 MANAGING SYNCHRONOUS AND ASYNCHRONOUS SYSTEM MANAGEMENT INTERRUPTS

When coding for a multiprocessor system or a system with Intel HT Technology, it was not always possible for an SMI handler to distinguish between a synchronous SMI (triggered during an I/O instruction) and an asynchronous SMI. To facilitate the discrimination of these two events, incremental state information has been added to the SMM state save map.

Processors that have an SMM revision ID of 30004H or higher have the incremental state information described below.

### 26.7.1 I/O State Implementation

Within the extended SMM state save map, a bit (IO\_SMI) is provided that is set only when an SMI is either taken immediately after a *successful* I/O instruction or is taken

## SYSTEM MANAGEMENT MODE

after a *successful* iteration of a REP I/O instruction (the *successful* notion pertains to the processor point of view; not necessarily to the corresponding platform function). When set, the IO\_SMI bit provides a strong indication that the corresponding SMI was synchronous. In this case, the SMM State Save Map also supplies the port address of the I/O operation. The IO\_SMI bit and the I/O Port Address may be used in conjunction with the information logged by the platform to confirm that the SMI was indeed synchronous.

The IO\_SMI bit by itself is a strong indication, not a guarantee, that the SMI is synchronous. This is because an asynchronous SMI might coincidentally be taken after an I/O instruction. In such a case, the IO\_SMI bit would still be set in the SMM state save map.

Information characterizing the I/O instruction is saved in two locations in the SMM State Save Map (Table 26-5). The IO\_SMI bit also serves as a valid bit for the rest of the I/O information fields. The contents of these I/O information fields are not defined when the IO\_SMI bit is not set.

**Table 26-5. I/O Instruction Information in the SMM State Save Map**

| State (SMM Rev. ID: 30004H or higher)         | Format             |          |    |          |   |          |   |            |        |
|-----------------------------------------------|--------------------|----------|----|----------|---|----------|---|------------|--------|
|                                               | 31                 | 16       | 15 | 8        | 7 | 4        | 3 | 1          | 0      |
| I/O State Field<br>SMRAM offset 7FA4          |                    | I/O Port |    | Reserved |   | I/O Type |   | I/O Length | IO_SMI |
|                                               | 31                 |          |    |          |   |          |   | 0          |        |
| I/O Memory Address Field<br>SMRAM offset 7FA0 | I/O Memory Address |          |    |          |   |          |   |            |        |

When IO\_SMI is set, the other fields may be interpreted as follows:

- I/O length:
  - 001 – Byte
  - 010 – Word
  - 100 – Dword
- I/O instruction type (Table 26-6)

**Table 26-6. I/O Instruction Type Encodings**

| Instruction   | Encoding |
|---------------|----------|
| IN Immediate  | 1001     |
| IN DX         | 0001     |
| OUT Immediate | 1000     |

Table 26-6. I/O Instruction Type Encodings (Contd.)

| Instruction | Encoding |
|-------------|----------|
| OUT DX      | 0000     |
| INS         | 0011     |
| OUTS        | 0010     |
| REP INS     | 0111     |
| REP OUTS    | 0110     |

## 26.8 NMI HANDLING WHILE IN SMM

NMI interrupts are blocked upon entry to the SMI handler. If an NMI request occurs during the SMI handler, it is latched and serviced after the processor exits SMM. Only one NMI request will be latched during the SMI handler. If an NMI request is pending when the processor executes the RSM instruction, the NMI is serviced before the next instruction of the interrupted code sequence. This assumes that NMIs were not blocked before the SMI occurred. If NMIs were blocked before the SMI occurred, they are blocked after execution of RSM.

Although NMI requests are blocked when the processor enters SMM, they may be enabled through software by executing an IRET instruction. If the SMM handler requires the use of NMI interrupts, it should invoke a dummy interrupt service routine for the purpose of executing an IRET instruction. Once an IRET instruction is executed, NMI interrupt requests are serviced in the same “real mode” manner in which they are handled outside of SMM.

A special case can occur if an SMI handler nests inside an NMI handler and then another NMI occurs. During NMI interrupt handling, NMI interrupts are disabled, so normally NMI interrupts are serviced and completed with an IRET instruction one at a time. When the processor enters SMM while executing an NMI handler, the processor saves the SMRAM state save map but does not save the attribute to keep NMI interrupts disabled. Potentially, an NMI could be latched (while in SMM or upon exit) and serviced upon exit of SMM even though the previous NMI handler has still not completed. One or more NMIs could thus be nested inside the first NMI handler. The NMI interrupt handler should take this possibility into consideration.

Also, for the Pentium processor, exceptions that invoke a trap or fault handler will enable NMI interrupts from inside of SMM. This behavior is implementation specific for the Pentium processor and is not part of the IA-32 architecture.

## 26.9 SMM REVISION IDENTIFIER

The SMM revision identifier field is used to indicate the version of SMM and the SMM extensions that are supported by the processor (see Figure 26-2). The SMM revision identifier is written during SMM entry and can be examined in SMRAM space at offset

## SYSTEM MANAGEMENT MODE

7EFCH. The lower word of the SMM revision identifier refers to the version of the base SMM architecture.

Figure 26-2. SMM Revision Identifier

The upper word of the SMM revision identifier refers to the extensions available. If the I/O instruction restart flag (bit 16) is set, the processor supports the I/O instruction restart (see Section 26.12); if the SMBASE relocation flag (bit 17) is set, SMRAM base address relocation is supported (see Section 26.11).

## 26.10 AUTO HALT RESTART

If the processor is in a HALT state (due to the prior execution of a HLT instruction) when it receives an SMI, the processor records the fact in the auto HALT restart flag in the saved processor state (see Figure 26-3). (This flag is located at offset 7F02H and bit 0 in the state save area of the SMRAM.)

If the processor sets the auto HALT restart flag upon entering SMM (indicating that the SMI occurred when the processor was in the HALT state), the SMI handler has two options:

- It can leave the auto HALT restart flag set, which instructs the RSM instruction to return program control to the HLT instruction. This option in effect causes the processor to re-enter the HALT state after handling the SMI. (This is the default operation.)
- It can clear the auto HALT restart flag, with instructs the RSM instruction to return program control to the instruction following the HLT instruction.

Figure 26-3. Auto HALT Restart Field

These options are summarized in Table 26-7. If the processor was not in a HALT state when the SMI was received (the auto HALT restart flag is cleared), setting the flag to 1 will cause unpredictable behavior when the RSM instruction is executed.

Table 26-7. Auto HALT Restart Flag Values

| Value of Flag After Entry to SMM | Value of Flag When Exiting SMM | Action of Processor When Exiting SMM                        |
|----------------------------------|--------------------------------|-------------------------------------------------------------|
| 0                                | 0                              | Returns to next instruction in interrupted program or task. |
| 0                                | 1                              | Unpredictable.                                              |
| 1                                | 0                              | Returns to next instruction after HLT instruction.          |
| 1                                | 1                              | Returns to HALT state.                                      |

If the HLT instruction is restarted, the processor will generate a memory access to fetch the HLT instruction (if it is not in the internal cache), and execute a HLT bus transaction. This behavior results in multiple HLT bus transactions for the same HLT instruction.

### 26.10.1 Executing the HLT Instruction in SMM

The HLT instruction should not be executed during SMM, unless interrupts have been enabled by setting the IF flag in the EFLAGS register. If the processor is halted in SMM, the only event that can remove the processor from this state is a maskable hardware interrupt or a hardware reset.

## 26.11 SMBASE RELOCATION

The default base address for the SMRAM is 30000H. This value is contained in an internal processor register called the SMBASE register. The operating system or executive can relocate the SMRAM by setting the SMBASE field in the saved state map (at offset 7EF8H) to a new value (see Figure 26-4). The RSM instruction reloads the internal SMBASE register with the value in the SMBASE field each time it exits SMM. All subsequent SMI requests will use the new SMBASE value to find the starting

## SYSTEM MANAGEMENT MODE

address for the SMI handler (at SMBASE + 8000H) and the SMRAM state save area (from SMBASE + FEO0H to SMBASE + FFFFH). (The processor resets the value in its internal SMBASE register to 30000H on a RESET, but does not change it on an INIT.)

Figure 26-4. SMBASE Relocation Field

In multiple-processor systems, initialization software must adjust the SMBASE value for each processor so that the SMRAM state save areas for each processor do not overlap. (For Pentium and Intel486 processors, the SMBASE values must be aligned on a 32-KByte boundary or the processor will enter shutdown state during the execution of a RSM instruction.)

If the SMBASE relocation flag in the SMM revision identifier field is set, it indicates the ability to relocate the SMBASE (see Section 26.9).

### 26.11.1 Relocating SMRAM to an Address Above 1 MByte

In SMM, the segment base registers can only be updated by changing the value in the segment registers. The segment registers contain only 16 bits, which allows only 20 bits to be used for a segment base address (the segment register is shifted left 4 bits to determine the segment base address). If SMRAM is relocated to an address above 1 MByte, software operating in real-address mode can no longer initialize the segment registers to point to the SMRAM base address (SMBASE).

The SMRAM can still be accessed by using 32-bit address-size override prefixes to generate an offset to the correct address. For example, if the SMBASE has been relocated to FFFFFFFH (immediately below the 16-MByte boundary) and the DS, ES, FS, and GS registers are still initialized to 0H, data in SMRAM can be accessed by using 32-bit displacement registers, as in the following example:

```
mov    esi,00FFxxxxH; 64K segment immediately below 16M
mov    ax,ds:[esi]
```

A stack located above the 1-MByte boundary can be accessed in the same manner.

## 26.12 I/O INSTRUCTION RESTART

If the I/O instruction restart flag in the SMM revision identifier field is set (see Section 26.9), the I/O instruction restart mechanism is present on the processor. This mechanism allows an interrupted I/O instruction to be re-executed upon returning from

SMM mode. For example, if an I/O instruction is used to access a powered-down I/O device, a chip set supporting this device can intercept the access and respond by asserting SMI#. This action invokes the SMI handler to power-up the device. Upon returning from the SMI handler, the I/O instruction restart mechanism can be used to re-execute the I/O instruction that caused the SMI.

The I/O instruction restart field (at offset 7F00H in the SMM state-save area, see Figure 26-5) controls I/O instruction restart. When an RSM instruction is executed, if this field contains the value FFH, then the EIP register is modified to point to the I/O instruction that received the SMI request. The processor will then automatically re-execute the I/O instruction that the SMI trapped. (The processor saves the necessary machine state to insure that re-execution of the instruction is handled coherently.)

Figure 26-5. I/O Instruction Restart Field

If the I/O instruction restart field contains the value 00H when the RSM instruction is executed, then the processor begins program execution with the instruction following the I/O instruction. (When a repeat prefix is being used, the next instruction may be the next I/O instruction in the repeat loop.) Not re-executing the interrupted I/O instruction is the default behavior; the processor automatically initializes the I/O instruction restart field to 00H upon entering SMM. Table 26-8 summarizes the states of the I/O instruction restart field.

Table 26-8. I/O Instruction Restart Field Values

| Value of Flag After Entry to SMM | Value of Flag When Exiting SMM | Action of Processor When Exiting SMM         |
|----------------------------------|--------------------------------|----------------------------------------------|
| 00H                              | 00H                            | Does not re-execute trapped I/O instruction. |
| 00H                              | FFH                            | Re-executes trapped I/O instruction.         |

The I/O instruction restart mechanism does not indicate the cause of the SMI. It is the responsibility of the SMI handler to examine the state of the processor to determine the cause of the SMI and to determine if an I/O instruction was interrupted and should be restarted upon exiting SMM. If an SMI interrupt is signaled on a non-I/O instruction boundary, setting the I/O instruction restart field to FFH prior to executing the RSM instruction will likely result in a program error.

## SYSTEM MANAGEMENT MODE

### 26.12.1 Back-to-Back SMI Interrupts When I/O Instruction Restart Is Being Used

If an SMI interrupt is signaled while the processor is servicing an SMI interrupt that occurred on an I/O instruction boundary, the processor will service the new SMI request before restarting the originally interrupted I/O instruction. If the I/O instruction restart field is set to FFH prior to returning from the second SMI handler, the EIP will point to an address different from the originally interrupted I/O instruction, which will likely lead to a program error. To avoid this situation, the SMI handler must be able to recognize the occurrence of back-to-back SMI interrupts when I/O instruction restart is being used and insure that the handler sets the I/O instruction restart field to 00H prior to returning from the second invocation of the SMI handler.

## 26.13 SMM MULTIPLE-PROCESSOR CONSIDERATIONS

The following should be noted when designing multiple-processor systems:

- Any processor in a multiprocessor system can respond to an SMM.
- Each processor needs its own SMRAM space. This space can be in system memory or in a separate RAM.
- The SMRAMs for different processors can be overlapped in the same memory space. The only stipulation is that each processor needs its own state save area and its own dynamic data storage area. (Also, for the Pentium and Intel486 processors, the SMBASE address must be located on a 32-KByte boundary.) Code and static data can be shared among processors. Overlapping SMRAM spaces can be done more efficiently with the P6 family processors because they do not require that the SMBASE address be on a 32-KByte boundary.
- The SMI handler will need to initialize the SMBASE for each processor.
- Processors can respond to local SMIs through their SMI# pins or to SMIs received through the APIC interface. The APIC interface can distribute SMIs to different processors.
- Two or more processors can be executing in SMM at the same time.
- When operating Pentium processors in dual processing (DP) mode, the SMIACT# pin is driven only by the MRM processor and should be sampled with ADS#. For additional details, see Chapter 14 of the *Pentium Processor Family User's Manual, Volume 1*.

SMM is not re-entrant, because the SMRAM State Save Map is fixed relative to the SMBASE. If there is a need to support two or more processors in SMM mode at the same time then each processor should have dedicated SMRAM spaces. This can be done by using the SMBASE Relocation feature (see Section 26.11).

## 26.14 DEFAULT TREATMENT OF SMIS AND SMM WITH VMX OPERATION AND SMX OPERATION

Under the default treatment, the interactions of SMIs and SMM with VMX operation are few. This section details those interactions. It also explains how this treatment affects SMX operation.

### 26.14.1 Default Treatment of SMI Delivery

Ordinary SMI delivery saves processor state into SMRAM and then loads state based on architectural definitions. Under the default treatment, processors that support VMX operation perform SMI delivery as follows:

```

enter SMM;
save the following internal to the processor:
CR4.VMXE
    an indication of whether the logical processor was in VMX operation (root or non-root)
IF the logical processor is in VMX operation
    THEN
        save current VMCS pointer internal to the processor;
        leave VMX operation;
        save VMX-critical state defined below;
    FI;
IF the logical processor supports SMX operation
    THEN
        save internal to the logical processor an indication of whether the Intel® TXT private space
        is locked;
        IF the TXT private space is unlocked
            THEN lock the TXT private space;
        FI;
    FI;
CR4.VMXE ← 0;
perform ordinary SMI delivery:
    save processor state in SMRAM;
    set processor state to standard SMM values;1
    invalidate linear mappings and combined mappings associated with VPID 0000H (for all PCIDs);
    combined mappings for VPID 0000H are invalidated for all EP4TA values (EP4TA is the value of bits
    51:12 of EPTP; see Section 25.3);
The pseudocode above makes reference to the saving of VMX-critical state. This
state consists of the following: (1) SS.DPL (the current privilege level);
(2) RFLAGS.VM2; (3) the state of blocking by STI and by MOV SS (see Table 21-3 in

```

---

1. This causes the logical processor to block INIT signals, NMIs, and SMIs.

## SYSTEM MANAGEMENT MODE

Section 21.4.2); (4) the state of virtual-NMI blocking (only if the processor is in VMX non-root operation and the “virtual NMIs” VM-execution control is 1); and (5) an indication of whether an MTF VM exit is pending (see Section 22.7.2). These data may be saved internal to the processor or in the VMCS region of the current VMCS. Processors that do not support SMI recognition while there is blocking by STI or by MOV SS need not save the state of such blocking.

If the logical processor supports the 1-setting of the “enable EPT” VM-execution control and the logical processor was in VMX non-root operation at the time of an SMI, it saves the value of that control into bit 0 of the 32-bit field at offset SMBASE + 8000H + 7EE0H (SMBASE + FEE0H; see Table 26-3).<sup>1</sup> If the logical processor was not in VMX non-root operation at the time of the SMI, it saves 0 into that bit. If the logical processor saves 1 into that bit (it was in VMX non-root operation and the “enable EPT” VM-execution control was 1), it saves the value of the EPT pointer (EPTP) into the 64-bit field at offset SMBASE + 8000H + 7ED8H (SMBASE + FED8H).

Because SMI delivery causes a logical processor to leave VMX operation, all the controls associated with VMX non-root operation are disabled in SMM and thus cannot cause VM exits while the logical processor is in SMM.

### 26.14.2 Default Treatment of RSM

Ordinary execution of RSM restores processor state from SMRAM. Under the default treatment, processors that support VMX operation perform RSM as follows:

```
IF VMXE = 1 in CR4 image in SMRAM
  THEN fail and enter shutdown state;
ELSE
  restore state normally from SMRAM;
  invalidate linear mappings and combined mappings associated with all VPIDs and all PCIDs;
  combined mappings are invalidated for all EP4TA values (EP4TA is the value of bits 51:12 of EPTP;
  see Section 25.3);
  IF the logical processor supports SMX operation and the Intel® TXT private space was
  unlocked at the time of the last SMI (as saved)
    THEN unlock the TXT private space;
  FI;
  CR4.VMXE ← value stored internally;
```

- 
2. Section 26.14 and Section 26.15 use the notation RAX, RIP, RSP, RFLAGS, etc. for processor registers because most processors that support VMX operation also support Intel 64 architecture. For processors that do not support Intel 64 architecture, this notation refers to the 32-bit forms of these registers (EAX, EIP, ESP, EFLAGS, etc.). In a few places, notation such as EAX is used to refer specifically to the lower 32 bits of the register.
  1. “Enable EPT” is a secondary processor-based VM-execution control. If bit 31 of the primary processor-based VM-execution controls is 0, SMI functions as the “enable EPT” VM-execution control were 0. See Section 21.6.2.

IF internal storage indicates that the logical processor had been in VMX operation (root or non-root)

THEN

- enter VMX operation (root or non-root);
- restore VMX-critical state as defined in Section 26.14.1;
- set to their fixed values any bits in CRO and CR4 whose values must be fixed in VMX operation (see Section 20.8);<sup>1</sup>
- IF RFLAGS.VM = 0 AND (in VMX root operation OR the “unrestricted guest” VM-execution control is 0)<sup>2</sup>

THEN

- CS.RPL ← SS.DPL;
- SS.RPL ← SS.DPL;

FI;

restore current VMCS pointer;

FI;

leave SMM;

IF logical processor will be in VMX operation or in SMX operation after RSM

THEN block A20M and leave A20M mode;

FI;

FI;

RSM unblocks SMIs. It restores the state of blocking by NMI (see Table 21-3 in Section 21.4.2) as follows:

- If the RSM is not to VMX non-root operation or if the “virtual NMIs” VM-execution control will be 0, the state of NMI blocking is restored normally.
- If the RSM is to VMX non-root operation and the “virtual NMIs” VM-execution control will be 1, NMIs are not blocked after RSM. The state of virtual-NMI blocking is restored as part of VMX-critical state.

INIT signals are blocked after RSM if and only if the logical processor will be in VMX root operation.

If RSM returns a logical processor to VMX non-root operation, it re-establishes the controls associated with the current VMCS. If the “interrupt-window exiting” VM-execution control is 1, a VM exit occurs immediately after RSM if the enabling conditions apply. The same is true for the “NMI-window exiting” VM-execution control. Such VM exits occur with their normal priority. See Section 22.3.

- 
1. If the RSM is to VMX non-root operation and both the “unrestricted guest” VM-execution control and bit 31 of the primary processor-based VM-execution controls will be 1, CRO.PE and CRO.PG retain the values that were loaded from SMRAM regardless of what is reported in the capability MSR IA32\_VMX\_CRO\_FIXED0.
  2. “Unrestricted guest” is a secondary processor-based VM-execution control. If bit 31 of the primary processor-based VM-execution controls is 0, VM entry functions as if the “unrestricted guest” VM-execution control were 0. See Section 21.6.2.

## SYSTEM MANAGEMENT MODE

If an MTF VM exit was pending at the time of the previous SMI, an MTF VM exit is pending on the instruction boundary following execution of RSM. The following items detail the treatment of MTF VM exits that may be pending following RSM:

- System-management interrupts (SMIs), INIT signals, and higher priority events take priority over these MTF VM exits. These MTF VM exits take priority over debug-trap exceptions and lower priority events.
- These MTF VM exits wake the logical processor if RSM caused the logical processor to enter the HLT state (see Section 26.10). They do not occur if the logical processor just entered the shutdown state.

### 26.14.3 Protection of CR4.VMXE in SMM

Under the default treatment, CR4.VMXE is treated as a reserved bit while a logical processor is in SMM. Any attempt by software running in SMM to set this bit causes a general-protection exception. In addition, software cannot use VMX instructions or enter VMX operation while in SMM.

### 26.14.4 VMXOFF and SMI Unblocking

The VMXOFF instruction can be executed only with the default treatment (see Section 26.15.1) and only outside SMM. If SMIs are blocked when VMXOFF is executed, VMXOFF unblocks them unless IA32\_SMM\_MONITOR\_CTL[bit 2] is 1 (see Section 26.15.5 for details regarding this MSR).<sup>1</sup> Section 26.15.7 identifies a case in which SMIs may be blocked when VMXOFF is executed.

Not all processors allow this bit to be set to 1. Software should consult the VMX capability MSR IA32\_VMX\_MISC (see Appendix G.6) to determine whether this is allowed.

## 26.15 DUAL-MONITOR TREATMENT OF SMIs AND SMM

Dual-monitor treatment is activated through the cooperation of the **executive monitor** (the VMM that operates outside of SMM to provide basic virtualization) and the **SMM monitor** (the VMM that operates inside SMM—while in VMX operation—to support system-management functions). Control is transferred to the SMM monitor through VM exits; VM entries are used to return from SMM.

The dual-monitor treatment may not be supported by all processors. Software should consult the VMX capability MSR IA32\_VMX\_BASIC (see Appendix G.1) to determine whether it is supported.

---

1. Setting IA32\_SMM\_MONITOR\_CTL[bit 2] to 1 prevents VMXOFF from unblocking SMIs regardless of the value of the register's valid bit (bit 0).

### 26.15.1 Dual-Monitor Treatment Overview

The dual-monitor treatment uses an executive monitor and an SMM monitor. Transitions from the executive monitor or its guests to the SMM monitor are called **SMM VM exits** and are discussed in Section 26.15.2. SMM VM exits are caused by SMIs as well as executions of VMCALL in VMX root operation. The latter allow the executive monitor to call the SMM monitor for service.

The SMM monitor runs in VMX root operation and uses VMX instructions to establish a VMCS and perform VM entries to its own guests. This is done all inside SMM (see Section 26.15.3). The SMM monitor returns from SMM, not by using the RSM instruction, but by using a VM entry that returns from SMM. Such VM entries are described in Section 26.15.4.

Initially, there is no SMM monitor and the default treatment (Section 26.14) is used. The dual-monitor treatment is not used until it is enabled and activated. The steps to do this are described in Section 26.15.5 and Section 26.15.6.

It is not possible to leave VMX operation under the dual-monitor treatment; VMXOFF will fail if executed. The dual-monitor treatment must be deactivated first. The SMM monitor deactivates dual-monitor treatment using a VM entry that returns from SMM with the “deactivate dual-monitor treatment” VM-entry control set to 1 (see Section 26.15.7).

The executive monitor configures any VMCS that it uses for VM exits to the executive monitor. SMM VM exits, which transfer control to the SMM monitor, use a different VMCS. Under the dual-monitor treatment, each logical processor uses a separate VMCS called the **SMM-transfer VMCS**. When the dual-monitor treatment is active, the logical processor maintains another VMCS pointer called the **SMM-transfer VMCS pointer**. The SMM-transfer VMCS pointer is established when the dual-monitor treatment is activated.

### 26.15.2 SMM VM Exits

An SMM VM exit is a VM exit that begins outside SMM and that ends in SMM.

Unlike other VM exits, SMM VM exits can begin in VMX root operation. SMM VM exits result from the arrival of an SMI outside SMM or from execution of VMCALL in VMX root operation outside SMM. Execution of VMCALL in VMX root operation causes an SMM VM exit only if the valid bit is set in the IA32\_SMM\_MONITOR\_CTL MSR (see Section 26.15.5).

Execution of VMCALL in VMX root operation causes an SMM VM exit even under the default treatment. This SMM VM exit activates the dual-monitor treatment (see Section 26.15.6).

Differences between SMM VM exits and other VM exits are detailed in Sections 26.15.2.1 through 26.15.2.5. Differences between SMM VM exits that activate the dual-monitor treatment and other SMM VM exits are described in Section 26.15.6.

## SYSTEM MANAGEMENT MODE

### 26.15.2.1 Architectural State Before a VM Exit

System-management interrupts (SMIs) that cause SMM VM exits always do so directly. They do not save state to SMRAM as they do under the default treatment.

### 26.15.2.2 Updating the Current-VMCS and Executive-VMCS Pointers

SMM VM exits begin by performing the following steps:

1. The executive-VMCS pointer field in the SMM-transfer VMCS is loaded as follows:
  - If the SMM VM exit commenced in VMX non-root operation, it receives the current-VMCS pointer.
  - If the SMM VM exit commenced in VMX root operation, it receives the VMXON pointer.
2. The current-VMCS pointer is loaded with the value of the SMM-transfer VMCS pointer.

The last step ensures that the current VMCS is the SMM-transfer VMCS. VM-exit information is recorded in that VMCS, and VM-entry control fields in that VMCS are updated. State is saved into the guest-state area of that VMCS. The VM-exit controls and host-state area of that VMCS determine how the VM exit operates.

### 26.15.2.3 Recording VM-Exit Information

SMM VM exits differ from other VM exit with regard to the way they record VM-exit information. The differences follow.

- **Exit reason.**
  - Bits 15:0 of this field contain the basic exit reason. The field is loaded with the reason for the SMM VM exit: I/O SMI (an SMI arrived immediately after retirement of an I/O instruction), other SMI, or VMCALL. See Appendix I, “VMX Basic Exit Reasons”.
  - SMM VM exits are the only VM exits that may occur in VMX root operation. Because the SMM monitor may need to know whether it was invoked from VMX root or VMX non-root operation, this information is stored in bit 29 of the exit-reason field (see Table 21-13 in Section 21.9.1). The bit is set by SMM VM exits from VMX root operation.
  - If the SMM VM exit occurred in VMX non-root operation and an MTF VM exit was pending, bit 28 of the exit-reason field is set; otherwise, it is cleared.
  - Bits 27:16 and bits 31:30 are cleared.
- **Exit qualification.** For an SMM VM exit due an SMI that arrives immediately after the retirement of an I/O instruction, the exit qualification contains information about the I/O instruction that retired immediately before the SMI. It has the format given in Table 26-9.

**Table 26-9. Exit Qualification for SMIs That Arrive Immediately After the Retirement of an I/O Instruction**

| Bit Position(s) | Contents                                                                                         |
|-----------------|--------------------------------------------------------------------------------------------------|
| 2:0             | Size of access:<br>0 = 1-byte<br>1 = 2-byte<br>3 = 4-byte<br><br>Other values not used.          |
| 3               | Direction of the attempted access (0 = OUT, 1 = IN)                                              |
| 4               | String instruction (0 = not string; 1 = string)                                                  |
| 5               | REP prefixed (0 = not REP; 1 = REP)                                                              |
| 6               | Operand encoding (0 = DX, 1 = immediate)                                                         |
| 15:7            | Reserved (cleared to 0)                                                                          |
| 31:16           | Port number (as specified in the I/O instruction)                                                |
| 63:32           | Reserved (cleared to 0). These bits exist only on processors that support Intel 64 architecture. |

- **Guest linear address.** This field is used for VM exits due to SMIs that arrive immediately after the retirement of an INS or OUTS instruction for which the relevant segment (ES for INS; DS for OUTS unless overridden by an instruction prefix) is usable. The field receives the value of the linear address generated by ES:(E)DI (for INS) or segment:(E)SI (for OUTS; the default segment is DS but can be overridden by a segment override prefix) at the time the instruction started. If the relevant segment is not usable, the value is undefined. On processors that support Intel 64 architecture, bits 63:32 are clear if the logical processor was not in 64-bit mode before the VM exit.
- **I/O RCX, I/O RSI, I/O RDI, and I/O RIP.** For an SMM VM exit due an SMI that arrives immediately after the retirement of an I/O instruction, these fields receive the values that were in RCX, RSI, RDI, and RIP, respectively, before the I/O instruction executed. Thus, the value saved for I/O RIP addresses the I/O instruction.

#### 26.15.2.4 Saving Guest State

SMM VM exits save the contents of the SMBASE register into the corresponding field in the guest-state area.

## SYSTEM MANAGEMENT MODE

The value of the VMX-preemption timer is saved into the corresponding field in the guest-state area if the “save VMX-preemption timer value” VM-exit control is 1. That field becomes undefined if, in addition, either the SMM VM exit is from VMX root operation or the SMM VM exit is from VMX non-root operation and the “activate VMX-preemption timer” VM-execution control is 0.

### 26.15.2.5 Updating Non-Register State

SMM VM exits affect the non-register state of a logical processor as follows:

- SMM VM exits cause non-maskable interrupts (NMIs) to be blocked; they may be unblocked through execution of IRET or through a VM entry (depending on the value loaded for the interruptibility state and the setting of the “virtual NMIs” VM-execution control).
- SMM VM exits cause SMIs to be blocked; they may be unblocked by a VM entry that returns from SMM (see Section 26.15.4).

SMM VM exits invalidate linear mappings and combined mappings associated with VPID 0000H for all PCIDs. Combined mappings for VPID 0000H are invalidated for all EP4TA values (EP4TA is the value of bits 51:12 of EPTP; see Section 25.3). (Ordinary VM exits are not required to perform such invalidation if the “enable VPID” VM-execution control is 1; see Section 24.5.5.)

### 26.15.3 Operation of an SMM Monitor

Once invoked, an SMM monitor is in VMX root operation and can use VMX instructions to configure VMCSs and to cause VM entries to virtual machines supported by those structures. As noted in Section 26.15.1, the VMXOFF instruction cannot be used under the dual-monitor treatment and thus cannot be used by an SMM monitor.

The RSM instruction also cannot be used under the dual-monitor treatment. As noted in Section 22.1.3, it causes a VM exit if executed in SMM in VMX non-root operation. If executed in VMX root operation, it causes an invalid-opcode exception. SMM monitor uses VM entries to return from SMM (see Section 26.15.4).

### 26.15.4 VM Entries that Return from SMM

The SMM monitor returns from SMM using a VM entry with the “entry to SMM” VM-entry control clear. VM entries that return from SMM reverse the effects of an SMM VM exit (see Section 26.15.2).

VM entries that return from SMM may differ from other VM entries in that they do not necessarily enter VMX non-root operation. If the executive-VMCS pointer field in the current VMCS contains the VMXON pointer, the logical processor remains in VMX root operation after VM entry.

For differences between VM entries that return from SMM and other VM entries see Sections 26.15.4.1 through 26.15.4.10.

#### 26.15.4.1 Checks on the Executive-VMCS Pointer Field

VM entries that return from SMM perform the following checks on the executive-VMCS pointer field in the current VMCS:

- Bits 11:0 must be 0.
- The pointer must not set any bits beyond the processor's physical-address width.<sup>1,2</sup>
- The 32 bits located in memory referenced by the physical address in the pointer must contain the processor's VMCS revision identifier (see Section 21.2).

The checks above are performed before the checks described in Section 26.15.4.2 and before any of the following checks:

- If the "deactivate dual-monitor treatment" VM-entry control is 0, the launch state of the executive VMCS (the VMCS referenced by the executive-VMCS pointer field) must be launched (see Section 21.10.3).
- If the "deactivate dual-monitor treatment" VM-entry control is 1, the executive-VMCS pointer field must contain the VMXON pointer (see Section 26.15.7).<sup>3</sup>

#### 26.15.4.2 Checks on VM-Execution Control Fields

VM entries that return from SMM differ from other VM entries with regard to the checks performed on the VM-execution control fields specified in Section 23.2.1.1. They do not apply the checks to the current VMCS. Instead, VM-entry behavior depends on whether the executive-VMCS pointer field contains the VMXON pointer:

- If the executive-VMCS pointer field contains the VMXON pointer (the VM entry remains in VMX root operation), the checks are not performed at all.
- If the executive-VMCS pointer field does not contain the VMXON pointer (the VM entry enters VMX non-root operation), the checks are performed on the VM-execution control fields in the executive VMCS (the VMCS referenced by the executive-VMCS pointer field in the current VMCS). These checks are performed after checking the executive-VMCS pointer field itself (for proper alignment).

Other VM entries ensure that, if "activate VMX-preemption timer" VM-execution control is 0, the "save VMX-preemption timer value" VM-exit control is also 0. This check is not performed by VM entries that return from SMM.

- 
1. Software can determine a processor's physical-address width by executing CPUID with 80000008H in EAX. The physical-address width is returned in bits 7:0 of EAX.
  2. If IA32\_VMX\_BASIC[48] is read as 1, this pointer must not set any bits in the range 63:32; see Appendix G.1.
  3. An SMM monitor can determine the VMXON pointer by reading the executive-VMCS pointer field in the current VMCS after the SMM VM exit that activates the dual-monitor treatment.

## SYSTEM MANAGEMENT MODE

### 26.15.4.3 Checks on VM-Entry Control Fields

VM entries that return from SMM differ from other VM entries with regard to the checks performed on the VM-entry control fields specified in Section 23.2.1.3.

Specifically, if the executive-VMCS pointer field contains the VMXON pointer (the VM entry remains in VMX root operation), the following must **not** all hold for the VM-entry interruption-information field:

- the valid bit (bit 31) in the VM-entry interruption-information field is 1
- the interruption type (bits 10:8) is not 7 (other event); and
- the vector (bits 7:0) is not 0 (pending MTF VM exit).

### 26.15.4.4 Checks on the Guest State Area

Section 23.3.1 specifies checks performed on fields in the guest-state area of the VMCS. Some of these checks are conditioned on the settings of certain VM-execution controls (e.g., “virtual NMIs” or “unrestricted guest”). VM entries that return from SMM modify these checks based on whether the executive-VMCS pointer field contains the VMXON pointer:<sup>1</sup>

- If the executive-VMCS pointer field contains the VMXON pointer (the VM entry remains in VMX root operation), the checks are performed as all relevant VM-execution controls were 0. (As a result, some checks may not be performed at all.)
- If the executive-VMCS pointer field does not contain the VMXON pointer (the VM entry enters VMX non-root operation), this check is performed based on the settings of the VM-execution controls in the executive VMCS (the VMCS referenced by the executive-VMCS pointer field in the current VMCS).

For VM entries that return from SMM, the activity-state field must not indicate the wait-for-SIPI state if the executive-VMCS pointer field contains the VMXON pointer (the VM entry is to VMX root operation).

### 26.15.4.5 Loading Guest State

VM entries that return from SMM load the SMBASE register from the SMBASE field.

VM entries that return from SMM invalidate linear mappings and combined mappings associated with all VPIDs. Combined mappings are invalidated for all EP4TA values (EP4TA is the value of bits 51:12 of EPTP; see Section 25.3). (Ordinary VM entries are required to perform such invalidation only for VPID 0000H and are not required to do even that if the “enable VPID” VM-execution control is 1; see Section 23.3.2.5.)

---

1. An SMM monitor can determine the VMXON pointer by reading the executive-VMCS pointer field in the current VMCS after the SMM VM exit that activates the dual-monitor treatment.

#### 26.15.4.6 VMX-Preemption Timer

A VM entry that returns from SMM activates the VMX-preemption timer only if the executive-VMCS pointer field does not contain the VMXON pointer (the VM entry enters VMX non-root operation) and the “activate VMX-preemption timer” VM-entry control is 1 in the executive VMCS (the VMCS referenced by the executive-VMCS pointer field). In this case, VM entry starts the VMX-preemption timer with the value in the VMX-preemption timer-value field in the current VMCS.

#### 26.15.4.7 Updating the Current-VMCS and SMM-Transfer VMCS Pointers

Successful VM entries (returning from SMM) load the SMM-transfer VMCS pointer with the current-VMCS pointer. Following this, they load the current-VMCS pointer from a field in the current VMCS:

- If the executive-VMCS pointer field contains the VMXON pointer (the VM entry remains in VMX root operation), the current-VMCS pointer is loaded from the VMCS-link pointer field.
- If the executive-VMCS pointer field does not contain the VMXON pointer (the VM entry enters VMX non-root operation), the current-VMCS pointer is loaded with the value of the executive-VMCS pointer field.

If the VM entry successfully enters VMX non-root operation, the VM-execution controls in effect after the VM entry are those from the new current VMCS. This includes any structures external to the VMCS referenced by VM-execution control fields.

The updating of these VMCS pointers occurs before event injection. Event injection is determined, however, by the VM-entry control fields in the VMCS that was current when the VM entry commenced.

#### 26.15.4.8 VM Exits Induced by VM Entry

Section 23.5.1.2 describes how the event-delivery process invoked by event injection may lead to a VM exit. Section 23.6.3 to Section 23.6.7 describe other situations that may cause a VM exit to occur immediately after a VM entry.

Whether these VM exits occur is determined by the VM-execution control fields in the current VMCS. For VM entries that return from SMM, they can occur only if the executive-VMCS pointer field does not contain the VMXON pointer (the VM entry enters VMX non-root operation).

In this case, determination is based on the VM-execution control fields in the VMCS that is current after the VM entry. This is the VMCS referenced by the value of the executive-VMCS pointer field at the time of the VM entry (see Section 26.15.4.7). This VMCS also controls the delivery of such VM exits. Thus, VM exits induced by a VM entry returning from SMM are to the executive monitor and not to the SMM monitor.

## SYSTEM MANAGEMENT MODE

### 26.15.4.9 SMI Blocking

VM entries that return from SMM determine the blocking of system-management interrupts (SMIs) as follows:

- If the “deactivate dual-monitor treatment” VM-entry control is 0, SMIs are blocked after VM entry if and only if the bit 2 in the interruptibility-state field is 1.
- If the “deactivate dual-monitor treatment” VM-entry control is 1, the blocking of SMIs depends on whether the logical processor is in SMX operation:<sup>1</sup>
  - If the logical processor is in SMX operation, SMIs are blocked after VM entry.
  - If the logical processor is outside SMX operation, SMIs are unblocked after VM entry.

VM entries that return from SMM and that do not deactivate the dual-monitor treatment may leave SMIs blocked. This feature exists to allow an SMM monitor to invoke functionality outside of SMM without unblocking SMIs.

### 26.15.4.10 Failures of VM Entries That Return from SMM

Section 23.7 describes the treatment of VM entries that fail during or after loading guest state. Such failures record information in the VM-exit information fields and load processor state as would be done on a VM exit. The VMCS used is the one that was current before the VM entry commenced. Control is thus transferred to the SMM monitor and the logical processor remains in SMM.

## 26.15.5 Enabling the Dual-Monitor Treatment

Code and data for the SMM monitor reside in a region of SMRAM called the **monitor segment** (MSEG). Code running in SMM determines the location of MSEG and establishes its content. This code is also responsible for enabling the dual-monitor treatment.

SMM code enables the dual-monitor treatment and determines the location of MSEG by writing to IA32\_SMM\_MONITOR\_CTL MSR (index 9BH). The MSR has the following format:

- Bit 0 is the register’s valid bit. The SMM monitor may be invoked using VMCALL only if this bit is 1. Because VMCALL is used to activate the dual-monitor treatment (see Section 26.15.6), the dual-monitor treatment cannot be activated if the bit is 0. This bit is cleared when the logical processor is reset.
- Bit 1 is reserved.

---

1. A logical processor is in SMX operation if GETSEC[SEXIT] has not been executed since the last execution of GETSEC[SENTER]. A logical processor is outside SMX operation if GETSEC[SENTER] has not been executed or if GETSEC[SEXIT] was executed after the last execution of GETSEC[SENTER]. See Chapter 6, “Safer Mode Extensions Reference,” in *Intel® 64 and IA-32 Architectures Software Developer’s Manual, Volume 2B*.

- Bit 2 determines whether executions of VMXOFF unblock SMIs under the default treatment of SMIs and SMM. Executions of VMXOFF unblock SMIs unless bit 2 is 1 (the value of bit 0 is irrelevant). See Section 26.14.4.

Certain leaf functions of the GETSEC instruction clear this bit (see Chapter 6, “Safer Mode Extensions Reference,” in *Intel® 64 and IA-32 Architectures Software Developer’s Manual, Volume 2B*)

- Bits 11:3 are reserved.
- Bits 31:12 contain a value that, when shifted right 12 bits, is the physical address of MSEG (the MSEG base address).
- Bits 63:32 are reserved.

The following items detail use of this MSR:

- The IA32\_SMM\_MONITOR\_CTL MSR is supported only on processors that support the dual-monitor treatment.<sup>1</sup> On other processors, accesses to the MSR using RDMSR or WRMSR generate a general-protection fault (#GP(0)).
- A write to the IA32\_SMM\_MONITOR\_CTL MSR using WRMSR generates a general-protection fault (#GP(0)) if executed outside of SMM or if an attempt is made to set any reserved bit. An attempt to write to IA32\_SMM\_MONITOR\_CTL MSR fails if made as part of a VM exit that does not end in SMM or part of a VM entry that does not begin in SMM.
- Reads from IA32\_SMM\_MONITOR\_CTL MSR using RDMSR are allowed any time RDMSR is allowed. The MSR may be read as part of any VM exit.
- The dual-monitor treatment can be activated only if the valid bit in the MSR is set to 1.

The 32 bytes located at the MSEG base address are called the **MSEG header**. The format of the MSEG header is given in Table 26-10 (each field is 32 bits).

Table 26-10. Format of MSEG Header

| Byte Offset | Field                           |
|-------------|---------------------------------|
| 0           | MSEG-header revision identifier |
| 4           | SMM-monitor features            |
| 8           | GDTR limit                      |
| 12          | GDTR base offset                |
| 16          | CS selector                     |
| 20          | EIP offset                      |

- 
- Software should consult the VMX capability MSR IA32\_VMX\_BASIC (see Appendix G.1) to determine whether the dual-monitor treatment is supported.

Table 26-10. Format of MSEG Header (Contd.)

| Byte Offset | Field      |
|-------------|------------|
| 24          | ESP offset |
| 28          | CR3 offset |

To ensure proper behavior in VMX operation, software should maintain the MSEG header in writeback cacheable memory. Future implementations may allow or require a different memory type.<sup>1</sup> Software should consult the VMX capability MSR IA32\_VMX\_BASIC (see Appendix G.1).

SMM code should enable the dual-monitor treatment (by setting the valid bit in IA32\_SMM\_MONITOR\_CTL MSR) only after establishing the content of the MSEG header as follows:

- Bytes 3:0 contain the **MSEG revision identifier**. Different processors may use different MSEG revision identifiers. These identifiers enable software to avoid using an MSEG header formatted for one processor on a processor that uses a different format. Software can discover the MSEG revision identifier that a processor uses by reading the VMX capability MSR IA32\_VMX\_MISC (see Appendix G.6).
- Bytes 7:4 contain the **SMM-monitor features** field. Bits 31:1 of this field are reserved and must be zero. Bit 0 of the field is the **IA-32e mode SMM feature bit**. It indicates whether the logical processor will be in IA-32e mode after the SMM monitor is activated (see Section 26.15.6).
- Bytes 31:8 contain fields that determine how processor state is loaded when the SMM monitor is activated (see Section 26.15.6.4). SMM code should establish these fields so that activating of the SMM monitor invokes the SMM monitor's initialization code.

## 26.15.6 Activating the Dual-Monitor Treatment

The dual-monitor treatment may be enabled by SMM code as described in Section 26.15.5. The dual-monitor treatment is activated only if it is enabled and only by the executive monitor. The executive monitor activates the dual-monitor treatment by executing VMCALL in VMX root operation.

When VMCALL activates the dual-monitor treatment, it causes an SMM VM exit. Differences between this SMM VM exit and other SMM VM exits are discussed in

- 
1. Alternatively, software may map the MSEG header with the UC memory type; this may be necessary, depending on how memory is organized. Doing so is strongly discouraged unless necessary as it will cause the performance of transitions using those structures to suffer significantly. In addition, the processor will continue to use the memory type reported in the VMX capability MSR IA32\_VMX\_BASIC with exceptions noted in Appendix G.1.

Sections 26.15.6.1 through 26.15.6.5. See also “VMCALL—Call to VM Monitor” in Chapter 6 of *Intel® 64 and IA-32 Architectures Software Developer’s Manual, Volume 2B*.

### 26.15.6.1 Initial Checks

An execution of VMCALL attempts to activate the dual-monitor treatment if (1) the processor supports the dual-monitor treatment;<sup>1</sup> (2) the logical processor is in VMX root operation; (3) the logical processor is outside SMM and the valid bit is set in the IA32\_SMM\_MONITOR\_CTL MSR; (4) the logical processor is not in virtual-8086 mode and not in compatibility mode; (5) CPL = 0; and (6) the dual-monitor treatment is not active.

The VMCS that manages SMM VM exit caused by this VMCALL is the current VMCS established by the executive monitor. The VMCALL performs the following checks on the current VMCS in the order indicated:

1. There must be a current VMCS pointer.
2. The launch state of the current VMCS must be clear.
3. The VM-exit control fields must be valid:
  - Reserved bits in the VM-exit controls must be set properly. Software may consult the VMX capability MSR IA32\_VMX\_EXIT\_CTLS to determine the proper settings (see Appendix G.4).
  - The following checks are performed for the VM-exit MSR-store address if the VM-exit MSR-store count field is non-zero:
    - The lower 4 bits of the VM-exit MSR-store address must be 0. The address should not set any bits beyond the processor’s physical-address width.<sup>2</sup>
    - The address of the last byte in the VM-exit MSR-store area should not set any bits beyond the processor’s physical-address width. The address of this last byte is VM-exit MSR-store address + (MSR count \* 16) – 1. (The arithmetic used for the computation uses more bits than the processor’s physical-address width.)

If IA32\_VMX\_BASIC[48] is read as 1, neither address should set any bits in the range 63:32; see Appendix G.1.

If any of these checks fail, subsequent checks are skipped and VMCALL fails. If all these checks succeed, the logical processor uses the IA32\_SMM\_MONITOR\_CTL MSR to determine the base address of MSEG. The following checks are performed in the order indicated:

- 
1. Software should consult the VMX capability MSR IA32\_VMX\_BASIC (see Appendix G.1) to determine whether the dual-monitor treatment is supported.
  2. Software can determine a processor’s physical-address width by executing CPUID with 80000008H in EAX. The physical-address width is returned in bits 7:0 of EAX.

## SYSTEM MANAGEMENT MODE

1. The logical processor reads the 32 bits at the base of MSEG and compares them to the processor's MSEG revision identifier.
2. The logical processor reads the SMM-monitor features field:
  - Bit 0 of the field is the IA-32e mode SMM feature bit, and it indicates whether the logical processor will be in IA-32e mode after the SMM monitor is activated.
    - If the VMCALL is executed on a processor that does not support Intel 64 architecture, the IA-32e mode SMM feature bit must be 0.
    - If the VMCALL is executed in 64-bit mode, the IA-32e mode SMM feature bit must be 1.
  - Bits 31:1 of this field are currently reserved and must be zero.

If any of these checks fail, subsequent checks are skipped and the VMCALL fails.

### 26.15.6.2 MSEG Checking

SMM VM exits that activate the dual-monitor treatment check the following before updating the current-VMCS pointer and the executive-VMCS pointer field (see Section 26.15.2.2):

- The 32 bits at the MSEG base address (used as a physical address) must contain the processor's MSEG revision identifier.
- Bits 31:1 of the SMM-monitor features field in the MSEG header (see Table 26-10) must be 0. Bit 0 of the field (the IA-32e mode SMM feature bit) must be 0 if the processor does not support Intel 64 architecture.

If either of these checks fail, execution of VMCALL fails.

### 26.15.6.3 Updating the Current-VMCS and Executive-VMCS Pointers

Before performing the steps in Section 26.15.2.2, SMM VM exits that activate the dual-monitor treatment begin by loading the SMM-transfer VMCS pointer with the value of the current-VMCS pointer.

### 26.15.6.4 Loading Host State

The VMCS that is current during an SMM VM exit that activates the dual-monitor treatment was established by the executive monitor. It does not contain the VM-exit controls and host state required to initialize the SMM monitor. For this reason, such SMM VM exits do not load processor state as described in Section 24.5. Instead, state is set to fixed values or loaded based on the content of the MSEG header (see Table 26-10):

- CRO is set to as follows:
  - PG, NE, ET, MP, and PE are all set to 1.

- CD and NW are left unchanged.
- All other bits are cleared to 0.
- CR3 is set as follows:
  - Bits 63:32 are cleared on processors that supports IA-32e mode.
  - Bits 31:12 are set to bits 31:12 of the sum of the MSEG base address and the CR3-offset field in the MSEG header.
  - Bits 11:5 and bits 2:0 are cleared (the corresponding bits in the CR3-offset field in the MSEG header are ignored).
  - Bits 4:3 are set to bits 4:3 of the CR3-offset field in the MSEG header.
- CR4 is set as follows:
  - MCE and PGE are cleared.
  - PAE is set to the value of the IA-32e mode SMM feature bit.
  - If the IA-32e mode SMM feature bit is clear, PSE is set to 1 if supported by the processor; if the bit is set, PSE is cleared.
  - All other bits are unchanged.
- DR7 is set to 400H.
- The IA32\_DEBUGCTL MSR is cleared to 00000000\_00000000H.
- The registers CS, SS, DS, ES, FS, and GS are loaded as follows:
  - All registers are usable.
  - CS.selector is loaded from the corresponding fields in the MSEG header (the high 16 bits are ignored), with bits 2:0 cleared to 0. If the result is 0000H, CS.selector is set to 0008H.
  - The selectors for SS, DS, ES, FS, and GS are set to CS.selector+0008H. If the result is 0000H (if the CS selector was 0xFFFF8), these selectors are instead set to 0008H.
  - The base addresses of all registers are cleared to zero.
  - The segment limits for all registers are set to FFFFFFFFH.
  - The AR bytes for the registers are set as follows:
    - CS.Type is set to 11 (execute/read, accessed, non-conforming code segment).
    - For SS, DS, FS, and GS, the Type is set to 3 (read/write, accessed, expand-up data segment).
    - The S bits for all registers are set to 1.
    - The DPL for each register is set to 0.
    - The P bits for all registers are set to 1.

## SYSTEM MANAGEMENT MODE

- On processors that support Intel 64 architecture, CS.L is loaded with the value of the IA-32e mode SMM feature bit.
- CS.D is loaded with the inverse of the value of the IA-32e mode SMM feature bit.
- For each of SS, DS, FS, and GS, the D/B bit is set to 1.
- The G bits for all registers are set to 1.
- LDTR is unusable. The LDTR selector is cleared to 0000H, and the register is otherwise undefined (although the base address is always canonical).
- GDTR.base is set to the sum of the MSEG base address and the GDTR base-offset field in the MSEG header (bits 63:32 are always cleared on processors that supports IA-32e mode). GDTR.limit is set to the corresponding field in the MSEG header (the high 16 bits are ignored).
- IDTR.base is unchanged. IDTR.limit is cleared to 0000H.
- RIP is set to the sum of the MSEG base address and the value of the RIP-offset field in the MSEG header (bits 63:32 are always cleared on logical processors that support IA-32e mode).
- RSP is set to the sum of the MSEG base address and the value of the RSP-offset field in the MSEG header (bits 63:32 are always cleared on logical processor that supports IA-32e mode).
- RFLAGS is cleared, except bit 1, which is always set.
- The logical processor is left in the active state.
- Event blocking after the SMM VM exit is as follows:
  - There is no blocking by STI or by MOV SS.
  - There is blocking by non-maskable interrupts (NMIs) and by SMIs.
- There are no pending debug exceptions after the SMM VM exit.
- For processors that support IA-32e mode, the IA32\_EFER MSR is modified so that LME and LMA both contain the value of the IA-32e mode SMM feature bit.

If any of CR3[63:5], CR4.PAE, CR4.PSE, or IA32\_EFER.LMA is changing, the TLBs are updated so that, after VM exit, the logical processor does not use translations that were cached before the transition. This is not necessary for changes that would not affect paging due to the settings of other bits (for example, changes to CR4.PSE if IA32\_EFER.LMA was 1 before and after the transition).

### 26.15.6.5 Loading MSRs

The VM-exit MSR-load area is not used by SMM VM exits that activate the dual-monitor treatment. No MSRs are loaded from that area.

### 26.15.7 Deactivating the Dual-Monitor Treatment

An SMM monitor may deactivate the dual monitor treatment and return the processor to default treatment of SMIs and SMM (see Section 26.14). It does this by executing a VM entry with the “deactivate dual-monitor treatment” VM-entry control set to 1.

As noted in Section 23.2.1.3 and Section 26.15.4.1, an attempt to deactivate the dual-monitor treatment fails in the following situations: (1) the processor is not in SMM; (2) the “entry to SMM” VM-entry control is 1; or (3) the executive-VMCS pointer does not contain the VMXON pointer (the VM entry is to VMX non-root operation).

As noted in Section 26.15.4.9, VM entries that deactivate the dual-monitor treatment ignore the SMI bit in the interruptibility-state field of the guest-state area. Instead, the blocking of SMIs following such a VM entry depends on whether the logical processor is in SMX operation:<sup>1</sup>

- If the logical processor is in SMX operation, SMIs are blocked after VM entry. SMIs may later be unblocked by the VMXOFF instruction (see Section 26.14.4) or by certain leaf functions of the GETSEC instruction (see Chapter 6, “Safer Mode Extensions Reference,” in *Intel® 64 and IA-32 Architectures Software Developer’s Manual, Volume 2B*).
- If the logical processor is outside SMX operation, SMIs are unblocked after VM entry.

## 26.16 SMI AND PROCESSOR EXTENDED STATE MANAGEMENT

On processors that support processor extended states using XSAVE/XRSTOR (see Chapter 13, “System Programming for Instruction Set Extensions and Processor Extended States”), the processor does not save any XSAVE/XRSTOR related state on an SMI. It is the responsibility of the SMM handler code to properly preserve the state information (including CR4.OSXSAVE, XCRO, and possibly processor extended states using XSAVE/XRSTOR). Therefore, the SMM handler must follow the rules described in Chapter 13.

---

1. A logical processor is in SMX operation if GETSEC[SEXIT] has not been executed since the last execution of GETSEC[SENTER]. A logical processor is outside SMX operation if GETSEC[SENTER] has not been executed or if GETSEC[SEXIT] was executed after the last execution of GETSEC[SENTER]. See Chapter 6, “Safer Mode Extensions Reference,” in *Intel® 64 and IA-32 Architectures Software Developer’s Manual, Volume 2B*.

## SYSTEM MANAGEMENT MODE

# CHAPTER 27

## VIRTUAL-MACHINE MONITOR PROGRAMMING CONSIDERATIONS

---

### 27.1 VMX SYSTEM PROGRAMMING OVERVIEW

The Virtual Machine Monitor (VMM) is a software class used to manage virtual machines (VM). This chapter describes programming considerations for VMMs.

Each VM behaves like a complete physical machine and can run operating system (OS) and applications. The VMM software layer runs at the most privileged level and has complete ownership of the underlying system hardware. The VMM controls creation of a VM, transfers control to a VM, and manages situations that can cause transitions between the guest VMs and host VMM. The VMM allows the VMs to share the underlying hardware and yet provides isolation between the VMs. The guest software executing in a VM is unaware of any transitions that might have occurred between the VM and its host.

### 27.2 SUPPORTING PROCESSOR OPERATING MODES IN GUEST ENVIRONMENTS

Typically, VMMs transfer control to a VM using VMX transitions referred to as VM entries. The boundary conditions that define what a VM is allowed to execute in isolation are specified in a virtual-machine control structure (VMCS).

As noted in Section 20.8, processors may fix certain bits in CRO and CR4 to specific values and not support other values. The first processors to support VMX operation require that CRO.PE and CRO.PG be 1 in VMX operation. Thus, a VM entry is allowed only to guests with paging enabled that are in protected mode or in virtual-8086 mode. Guest execution in other processor operating modes need to be specially handled by the VMM.

One example of such a condition is guest execution in real-mode. A VMM could support guest real-mode execution using at least two approaches:

- By using a fast instruction set emulator in the VMM.
- By using the similarity between real-mode and virtual-8086 mode to support real-mode guest execution in a virtual-8086 container. The virtual-8086 container may be implemented as a virtual-8086 container task within a monitor that emulates real-mode guest state and instructions, or by running the guest VM as the virtual-8086 container (by entering the guest with RFLAGS.VM<sup>1</sup> set). Attempts by real-mode code to access privileged state outside the virtual-8086 container would trap to the VMM and would also need to be emulated.

## VIRTUAL-MACHINE MONITOR PROGRAMMING CONSIDERATIONS

Another example of such a condition is guest execution in protected mode with paging disabled. A VMM could support such guest execution by using "identity" page tables to emulate unpaged protected mode.

### 27.2.1 Using Unrestricted Guest Mode

Processors which support the "unrestricted guest" VM-execution control allow VM software to run in real-address mode and unpaged protected mode. Since these modes do not use paging, VMM software must virtualize guest memory using EPT.

Special notes for 64-bit VMM software using the 1-setting of the "unrestricted guest" VM-execution control:

- It is recommended that 64-bit VMM software use the 1-settings of the "load IA32\_EFER" VM entry control and the "save IA32\_EFER" VM-exit control. If VM entry is establishing CR0.PG=0 and if the "IA-32e mode guest" and "load IA32\_EFER" VM entry controls are both 0, VM entry leaves IA32\_EFER.LME unmodified (i.e., the host value will persist in the guest).
- It is not necessary for VMM software to track guest transitions into and out of IA-32e mode for the purpose of maintaining the correct setting of the "IA-32e mode guest" VM entry control. This is because VM exits on processors supporting the 1-setting of the "unrestricted guest" VM-execution control save the (guest) value of IA32\_EFER.LMA into the "IA-32e mode guest" VM entry control.

## 27.3 MANAGING VMCS REGIONS AND POINTERS

A VMM must observe necessary procedures when working with a VMCS, the associated VMCS pointer, and the VMCS region. It must also not assume the state of persistency for VMCS regions in memory or cache.

Before entering VMX operation, the host VMM allocates a VMXON region. A VMM can host several virtual machines and have many VMCSs active under its management. A unique VMCS region is required for each virtual machine; a VMXON region is required for the VMM itself.

A VMM determines the VMCS region size by reading IA32\_VMX\_BASIC MSR; it creates VMCS regions of this size using a 4-KByte-aligned area of physical memory. Each VMCS region needs to be initialized with a VMCS revision identifier (at byte offset 0) identical to the revision reported by the processor in the VMX capability MSR.

---

1. This chapter uses the notation RAX, RIP, RSP, RFLAGS, etc. for processor registers because most processors that support VMX operation also support Intel 64 architecture. For processors that do not support Intel 64 architecture, this notation refers to the 32-bit forms of those registers (EAX, EIP, ESP, EFLAGS, etc.).

**NOTE**

Software must not read or write directly to the VMCS data region as the format is not architecturally defined. Consequently, Intel recommends that the VMM remove any linear-address mappings to VMCS regions before loading.

System software does not need to do special preparation to the VMXON region before entering into VMX operation. The address of the VMXON region for the VMM is provided as an operand to VMXON instruction. Once in VMX root operation, the VMM needs to prepare data fields in the VMCS that control the execution of a VM upon a VM entry. The VMM can make a VMCS the current VMCS by using the VMPTRLD instruction. VMCS data fields must be read or written only through VMREAD and VMWRITE commands respectively.

Every component of the VMCS is identified by a 32-bit encoding that is provided as an operand to VMREAD and VMWRITE. Appendix H provides the encodings. A VMM must properly initialize all fields in a VMCS before using the current VMCS for VM entry.

A VMCS is referred to as a controlling VMCS if it is the current VMCS on a logical processor in VMX non-root operation. A current VMCS for controlling a logical processor in VMX non-root operation may be referred to as a working VMCS if the logical processor is not in VMX non-root operation. The relationship of active, current (i.e. working) and controlling VMCS during VMX operation is shown in Figure 27-1.

**NOTE**

As noted in Section 21.1, the processor may optimize VMX operation by maintaining the state of an active VMCS (one for which VMPTRLD has been executed) on the processor. Before relinquishing control to other system software that may, without informing the VMM, remove power from the processor (e.g., for transitions to S3 or S4) or leave VMX operation, a VMM must VMCLEAR all active VMCSs. This ensures that all VMCS data cached by the processor are flushed to memory and that no other software can corrupt the current VMM's VMCS data. It is also recommended that the VMM execute VMXOFF after such executions of VMCLEAR.

The VMX capability MSR IA32\_VMX\_BASIC reports the memory type used by the processor for accessing a VMCS or any data structures referenced through pointers in the VMCS. Software must maintain the VMCS structures in cache-coherent memory. Software must always map the regions hosting the I/O bitmaps, MSR bitmaps, VM-exit MSR-store area, VM-exit MSR-load area, and VM-entry MSR-load area to the write-back (WB) memory type. Mapping these regions to uncacheable (UC) memory type is supported, but strongly discouraged due to negative impact on performance.

## VIRTUAL-MACHINE MONITOR PROGRAMMING CONSIDERATIONS

Figure 27-1. VMX Transitions and States of VMCS in a Logical Processor

## 27.4 USING VMX INSTRUCTIONS

VMX instructions are allowed only in VMX root operation. An attempt to execute a VMX instruction in VMX non-root operation causes a VM exit.

Processors perform various checks while executing any VMX instruction. They follow well-defined error handling on failures. VMX instruction execution failures detected before loading of a guest state are handled by the processor as follows:

- If the working-VMCS pointer is not valid, the instruction fails by setting RFLAGS.CF to 1.
- If the working-VMCS pointer is valid, RFLAGS.ZF is set to 1 and the proper error-code is saved in the VM-instruction error field of the working-VMCS.

Software is required to check RFLAGS.CF and RFLAGS.ZF to determine the success or failure of VMX instruction executions.

The following items provide details regarding use of the VM-entry instructions (VMLAUNCH and VMRESUME):

- If the working-VMCS pointer is valid, the state of the working VMCS may cause the VM-entry instruction to fail. RFLAGS.ZF is set to 1 and one of the following values is saved in the VM-instruction error field:
  - 4: VMLAUNCH with non-clear VMCS.  
If this error occurs, software can avoid the error by executing VMRESUME.
  - 5: VMRESUME with non-launched VMCS.  
If this error occurs, software can avoid the error by executing VMLAUNCH.
  - 6: VMRESUME after VMXOFF.<sup>1</sup>  
If this error occurs, software can avoid the error by executing the following sequence of instructions:
 

```
VMPTRST <working-VMCS pointer>
VMCLEAR <working-VMCS pointer>
VMPTRLD <working-VMCS pointer>
VMLAUNCH
```

(VMPTRST may not be necessary if software already knows the working-VMCS pointer.)
- If none of the above errors occur, the processor checks on the VMX controls and host-state area. If any of these checks fail, the VM-entry instruction fails. RFLAGS.ZF is set to 1 and either 7 (VM entry with invalid control field(s)) or 8 (VM entry with invalid host-state field(s)) is saved in the VM-instruction error field.
- After a VM-entry instruction (VMRESUME or VMLAUNCH) successfully completes the general checks and checks on VMX controls and the host-state area (see Section 23.2), any errors encountered while loading of guest-state (due to bad guest-state or bad MSR loading) causes the processor to load state from the host-state area of the working VMCS as if a VM exit had occurred (see Section 27.7).

---

1. Earlier versions of this manual described this error as "VMRESUME with a corrupted VMCS".

## VIRTUAL-MACHINE MONITOR PROGRAMMING CONSIDERATIONS

This failure behavior differs from that of VM exits in that no guest-state is saved to the guest-state area. A VMM can detect its VM-exit handler was invoked by such a failure by checking bit 31 (for 1) in the exit reason field of the working VMCS and further identify the failure by using the exit qualification field.

See Chapter 23 for more details about the VM-entry instructions.

## 27.5 VMM SETUP & TEAR DOWN

VMMs need to ensure that the processor is running in protected mode with paging before entering VMX operation. The following list describes the minimal steps required to enter VMX root operation with a VMM running at CPL = 0.

- Check VMX support in processor using CPUID.
- Determine the VMX capabilities supported by the processor through the VMX capability MSRs. See Section 27.5.1 and Appendix G.
- Create a VMXON region in non-pageable memory of a size specified by IA32\_VMX\_BASIC MSR and aligned to a 4-KByte boundary. Software should read the capability MSRs to determine width of the physical addresses that may be used for the VMXON region and ensure the entire VMXON region can be addressed by addresses with that width. Also, software must ensure that the VMXON region is hosted in cache-coherent memory.
- Initialize the version identifier in the VMXON region (the first 32 bits) with the VMCS revision identifier reported by capability MSRs.
- Ensure the current processor operating mode meets the required CRO fixed bits (CRO.PE = 1, CRO.PG = 1). Other required CRO fixed bits can be detected through the IA32\_VMX\_CRO\_FIXED0 and IA32\_VMX\_CRO\_FIXED1 MSRs.
- Enable VMX operation by setting CR4.VMXE = 1. Ensure the resultant CR4 value supports all the CR4 fixed bits reported in the IA32\_VMX\_CR4\_FIXED0 and IA32\_VMX\_CR4\_FIXED1 MSRs.
- Ensure that the IA32\_FEATURE\_CONTROL MSR (MSR index 3AH) has been properly programmed and that its lock bit is set (Bit 0 = 1). This MSR is generally configured by the BIOS using WRMSR.
- Execute VMXON with the physical address of the VMXON region as the operand. Check successful execution of VMXON by checking if RFLAGS.CF = 0.

Upon successful execution of the steps above, the processor is in VMX root operation.

A VMM executing in VMX root operation and CPL = 0 leaves VMX operation by executing VMXOFF and verifies successful execution by checking if RFLAGS.CF = 0 and RFLAGS.ZF = 0.

If an SMM monitor has been configured to service SMIs while in VMX operation (see Section 26.15), the SMM monitor needs to be torn down before the executive monitor can leave VMX operation (see Section 26.15.7). VMXOFF fails for the execu-

tive monitor (a VMM that entered VMX operation by way of issuing VMXON) if SMM monitor is configured.

### 27.5.1 Algorithms for Determining VMX Capabilities

As noted earlier, a VMM should determine the VMX capabilities supported by the processor by reading the VMX capability MSRs. The architecture for these MSRs is detailed in Appendix G.

As noted in Chapter 21, “Virtual-Machine Control Structures”, certain VMX controls are reserved and must be set to a specific value (0 or 1) determined by the processor. The specific value to which a reserved control must be set is its **default setting**. Most controls have a default setting of 0; Appendix G.2 identifies those controls that have a default setting of 1. The term **default1** describes the class of controls whose default setting is 1. The controls in this class from the pin-based VM-execution controls, the primary processor-based VM-execution controls, the VM-exit controls, and the VM-entry controls. There are no secondary processor-based VM-execution controls in the default1 class.

Future processors may define new functionality for one or more reserved controls. Such processors would allow each newly defined control to be set either to 0 or to 1. Software that does not desire a control’s new functionality should set the control to its default setting.

The capability MSRs IA32\_VMX\_PINBASED\_CTLs, IA32\_VMX\_PROCBASED\_CTLs, IA32\_VMX\_EXIT\_CTLs, and IA32\_VMX\_ENTRY\_CTLs report, respectively, on the allowed settings of most of the pin-based VM-execution controls, the primary processor-based VM-execution controls, the VM-exit controls, and the VM-entry controls. However, they will always report that any control in the default1 class must be 1. If a logical processor allows any control in the default1 class to be 0, it indicates this fact by returning 1 for the value of bit 55 of the IA32\_VMX\_BASIC MSR. If this bit is 1, the logical processor supports the capability MSRs IA32\_VMX\_TRUE\_PINBASED\_CTLs, IA32\_VMX\_TRUE\_PROCBASED\_CTLs, IA32\_VMX\_TRUE\_EXIT\_CTLs, and IA32\_VMX\_TRUE\_ENTRY\_CTLs. These capability MSRs report, respectively, on the allowed settings of all of the pin-based VM-execution controls, the primary processor-based VM-execution controls, the VM-exit controls, and the VM-entry controls.

Software may use one of the following high-level algorithms to determine the correct default control settings:<sup>1</sup>

1. The following algorithm does not use the details given in Appendix G.2:
  - a. Ignore bit 55 of the IA32\_VMX\_BASIC MSR.

---

1. These algorithms apply only to the pin-based VM-execution controls, the primary processor-based VM-execution controls, the VM-exit controls, and the VM-entry controls. Because there are no secondary processor-based VM-execution controls in the default1 class, a VMM can always set to 0 any such control whose meaning is unknown to it.

## VIRTUAL-MACHINE MONITOR PROGRAMMING CONSIDERATIONS

- b. Using RDMSR, read the VMX capability MSRs IA32\_VMX\_PINBASED\_CTLs, IA32\_VMX\_PROCBASED\_CTLs, IA32\_VMX\_EXIT\_CTLs, and IA32\_VMX\_ENTRY\_CTLs.
- c. Set the VMX controls as follows:
  - i) If the relevant VMX capability MSR reports that a control has a single setting, use that setting.
  - ii) If (1) the relevant VMX capability MSR reports that a control can be set to 0 or 1; and (2) the control's meaning is known to the VMM; then set the control based on functionality desired.
  - iii) If (1) the relevant VMX capability MSR reports that a control can be set to 0 or 1; and (2) the control's meaning is not known to the VMM; then set the control to 0.

A VMM using this algorithm will set to 1 all controls in the default1 class (in step (c)(i)). It will operate correctly even on processors that allow some controls in the default1 class to be 0. However, such a VMM will not be able to use the new features enabled by the 0-setting of such controls. For that reason, this algorithm is not recommended.

2. The following algorithm uses the details given in Appendix G.2. This algorithm requires software to know the identity of the controls in the default1 class:
  - a. Using RDMSR, read the IA32\_VMX\_BASIC MSR.
  - b. Use bit 55 of that MSR as follows:
    - i) If bit 55 is 0, use RDMSR to read the VMX capability MSRs IA32\_VMX\_PINBASED\_CTLs, IA32\_VMX\_PROCBASED\_CTLs, IA32\_VMX\_EXIT\_CTLs, and IA32\_VMX\_ENTRY\_CTLs.
    - ii) If bit 55 is 1, use RDMSR to read the VMX capability MSRs IA32\_VMX\_TRUE\_PINBASED\_CTLs, IA32\_VMX\_TRUE\_PROCBASED\_CTLs, IA32\_VMX\_TRUE\_EXIT\_CTLs, and IA32\_VMX\_TRUE\_ENTRY\_CTLs.
  - c. Set the VMX controls as follows:
    - i) If the relevant VMX capability MSR reports that a control has a single setting, use that setting.
    - ii) If (1) the relevant VMX capability MSR reports that a control can be set to 0 or 1; and (2) the control's meaning is known to the VMM; then set the control based on functionality desired.
    - iii) If (1) the relevant VMX capability MSR reports that a control can be set to 0 or 1; (2) the control's meaning is not known to the VMM; and (3) the control is not in the default1 class; then set the control to 0.
    - iv) If (1) the relevant VMX capability MSR reports that a control can be set to 0 or 1; (2) the control's meaning is not known to the VMM; and (3) the control is in the default1 class; then set the control to 1.

A VMM using this algorithm will set to 1 all controls in default1 class whose meaning it does not know (either in step (c)(i) or step (c)(iv)). It will operate correctly even on processors that allow some controls in the default1 class to be 0. Unlike a VMM using Algorithm 1, a VMM using Algorithm 2 will be able to use the new features enabled by the 0-setting of such controls.

3. The following algorithm uses the details given in Appendix G.2. This algorithm does not require software to know the identity of the controls in the default1 class:
  - a. Using RDMSR, read the VMX capability MSRs IA32\_VMX\_BASIC, IA32\_VMX\_PINBASED\_CTLs, IA32\_VMX\_PROCBASED\_CTLs, IA32\_VMX\_EXIT\_CTLs, and IA32\_VMX\_ENTRY\_CTLs.
  - b. If bit 55 of the IA32\_VMX\_BASIC MSR is 0, set the VMX controls as follows:
    - i) If the relevant VMX capability MSR reports that a control has a single setting, use that setting.
    - ii) If (1) the relevant VMX capability MSR reports that a control can be set to 0 or 1; and (2) the control's meaning is known to the VMM; then set the control based on functionality desired.
    - iii) If (1) the relevant VMX capability MSR reports that a control can be set to 0 or 1; and (2) the control's meaning is not known to the VMM; then set the control to 0.
  - c. If bit 55 of the IA32\_VMX\_BASIC MSR is 1, use RDMSR to read the VMX capability MSRs IA32\_VMX\_TRUE\_PINBASED\_CTLs, IA32\_VMX\_TRUE\_PROCBASED\_CTLs, IA32\_VMX\_TRUE\_EXIT\_CTLs, and IA32\_VMX\_TRUE\_ENTRY\_CTLs. Set the VMX controls as follows:
    - i) If the relevant VMX capability MSR just read reports that a control has a single setting, use that setting.
    - ii) If (1) the relevant VMX capability MSR just read reports that a control can be set to 0 or 1; and (2) the control's meaning is known to the VMM; then set the control based on functionality desired.
    - iii) If (1) the relevant VMX capability MSR just read reports that a control can be set to 0 or 1; (2) the control's meaning is not known to the VMM; and (3) the relevant VMX capability MSR as read in step (a) reports that a control can be set to 0; then set the control to 0.
    - iv) If (1) the relevant VMX capability MSR just read reports that a control can be set to 0 or 1; (2) the control's meaning is not known to the VMM; and (3) the relevant VMX capability MSR as read in step (a) reports that a control must be 1; then set the control to 1.

A VMM using this algorithm will set to 1 all controls in the default1 class whose meaning it does not know (in step (b)(i), step (c)(i), or step (c)(iv)). It will operate correctly even on processors that allow some controls in the default1 class to be 0. Unlike a VMM using Algorithm 1, a VMM using Algorithm 3 will be able to use the new features enabled by the 0-setting of such controls. Unlike a

## VIRTUAL-MACHINE MONITOR PROGRAMMING CONSIDERATIONS

VMM using Algorithm 2, a VMM using Algorithm 3 need not know the identities of the controls in the default1 class.

## 27.6 PREPARATION AND LAUNCHING A VIRTUAL MACHINE

The following list describes the minimal steps required by the VMM to set up and launch a guest VM.

- Create a VMCS region in non-pageable memory of size specified by the VMX capability MSR IA32\_VMX\_BASIC and aligned to 4-KBytes. Software should read the capability MSRs to determine width of the physical addresses that may be used for a VMCS region and ensure the entire VMCS region can be addressed by addresses with that width. The term “guest-VMCS address” refers to the physical address of the new VMCS region for the following steps.
- Initialize the version identifier in the VMCS (first 32 bits) with the VMCS revision identifier reported by the VMX capability MSR IA32\_VMX\_BASIC.
- Execute the VMCLEAR instruction by supplying the guest-VMCS address. This will initialize the new VMCS region in memory and set the launch state of the VMCS to “clear”. This action also invalidates the working-VMCS pointer register to FFFFFFFF\_FFFFFFFFH. Software should verify successful execution of VMCLEAR by checking if RFLAGS.CF = 0 and RFLAGS.ZF = 0.
- Execute the VMPTRLD instruction by supplying the guest-VMCS address. This initializes the working-VMCS pointer with the new VMCS region’s physical address.
- Issue a sequence of VMWRITEs to initialize various host-state area fields in the working VMCS. The initialization sets up the context and entry-points to the VMM upon subsequent VM exits from the guest. Host-state fields include control registers (CRO, CR3 and CR4), selector fields for the segment registers (CS, SS, DS, ES, FS, GS and TR), and base-address fields (for FS, GS, TR, GDTR and IDTR; RSP, RIP and the MSRs that control fast system calls).

Chapter 22 describes the host-state consistency checking done by the processor for VM entries. The VMM is required to set up host-state that comply with these consistency checks. For example, VMX requires the host-area to have a task register (TR) selector with TI and RPL fields set to 0 and pointing to a valid TSS.

- Use VMWRITEs to set up the various VM-exit control fields, VM-entry control fields, and VM-execution control fields in the VMCS. Care should be taken to make sure the settings of individual fields match the allowed 0 and 1 settings for the respective controls as reported by the VMX capability MSRs (see Appendix G). Any settings inconsistent with the settings reported by the capability MSRs will cause VM entries to fail.
- Use VMWRITE to initialize various guest-state area fields in the working VMCS. This sets up the context and entry-point for guest execution upon VM entry.

Chapter 22 describes the guest-state loading and checking done by the processor for VM entries to protected and virtual-8086 guest execution.

- The VMM is required to set up guest-state that complies with these consistency checks:
  - If the VMM design requires the initial VM launch to cause guest software (typically the guest virtual BIOS) execution from the guest's reset vector, it may need to initialize the guest execution state to reflect the state of a physical processor at power-on reset (described in Chapter 9, *Intel® 64 and IA-32 Architectures Software Developer's Manual, Volume 3A*).
  - The VMM may need to initialize additional guest execution state that is not captured in the VMCS guest-state area by loading them directly on the respective processor registers. Examples include general purpose registers, the CR2 control register, debug registers, floating point registers and so forth. VMM may support lazy loading of FPU, MMX, SSE, and SSE2 states with CRO.TS = 1 (described in *Intel® 64 and IA-32 Architectures Software Developer's Manual, Volume 3A*).
- Execute VMLAUNCH to launch the guest VM. If VMLAUNCH fails due to any consistency checks before guest-state loading, RFLAGS.CF or RFLAGS.ZF will be set and the VM-instruction error field (see Section 21.9.5) will contain the error-code. If guest-state consistency checks fail upon guest-state loading, the processor loads state from the host-state area as if a VM exit had occurred (see Section 27.6).

VMLAUNCH updates the controlling-VMCS pointer with the working-VMCS pointer and saves the old value of controlling-VMCS as the parent pointer. In addition, the launch state of the guest VMCS is changed to "launched" from "clear". Any programmed exit conditions will cause the guest to VM exit to the VMM. The VMM should execute VMRESUME instruction for subsequent VM entries to guests in a "launched" state.

## 27.7 HANDLING OF VM EXITS

This section provides examples of software steps involved in a VMM's handling of VM-exit conditions:

- Determine the exit reason through a VMREAD of the exit-reason field in the working-VMCS. Appendix I describes exit reasons and their encodings.
- VMREAD the exit-qualification from the VMCS if the exit-reason field provides a valid qualification. The exit-qualification field provides additional details on the VM-exit condition. For example, in case of page faults, the exit-qualification field provides the guest linear address that caused the page fault.
- Depending on the exit reason, fetch other relevant fields from the VMCS. Appendix I lists the various exit reasons.

- Handle the VM-exit condition appropriately in the VMM. This may involve the VMM emulating one or more guest instructions, programming the underlying host hardware resources, and then re-entering the VM to continue execution.

### 27.7.1 Handling VM Exits Due to Exceptions

As noted in Section 22.3, an exception causes a VM exit if the bit corresponding to the exception's vector is set in the exception bitmap. (For page faults, the error code also determines whether a VM exit occurs.) This section provide some guidelines of how a VMM might handle such exceptions.

Exceptions result when a logical processor encounters an unusual condition that software may not have expected. When guest software encounters an exception, it may be the case that the condition was caused by the guest software. For example, a guest application may attempt to access a page that is restricted to supervisor access. Alternatively, the condition causing the exception may have been established by the VMM. For example, a guest OS may attempt to access a page that the VMM has chosen to make not present.

When the condition causing an exception was established by guest software, the VMM may choose to **reflect** the exception to guest software. When the condition was established by the VMM itself, the VMM may choose to **resume** guest software after removing the condition.

#### 27.7.1.1 Reflecting Exceptions to Guest Software

If the VMM determines that a VM exit was caused by an exception due to a condition established by guest software, it may reflect that exception to guest software. The VMM would cause the exception to be delivered to guest software, where it can be handled as it would be if the guest were running on a physical machine. This section describes how that may be done.

In general, the VMM can deliver the exception to guest software using VM-entry event injection as described in Section 23.5. The VMM can copy (using VMREAD and VMWRITE) the contents of the VM-exit interruption-information field (which is valid, since the VM exit was caused by an exception) to the VM-entry interruption-information field (which, if valid, will cause the exception to be delivered as part of the next VM entry). The VMM would also copy the contents of the VM-exit interruption error-code field to the VM-entry exception error-code field; this need not be done if bit 11 (error code valid) is clear in the VM-exit interruption-information field. After this, the VMM can execute VMRESUME.

The following items provide details that may qualify the general approach:

- Care should be taken to ensure that reserved bits 30:12 in the VM-entry interruption-information field are 0. In particular, some VM exits may set bit 12 in the VM-exit interruption-information field to indicate NMI unblocking due to IRET. If this bit is copied as 1 into the VM-entry interruption-information field, the next VM entry will fail because that bit should be 0.

- Bit 31 (valid) of the IDT-vectoring information field indicates, if set, that the exception causing the VM exit occurred while another event was being delivered to guest software. If this is the case, it may not be appropriate simply to reflect that exception to guest software. To provide proper virtualization of the exception architecture, a VMM should handle nested events as a physical processor would. Processor handling is described in Chapter 6, “Interrupt 8—Double Fault Exception (#DF)” in *Intel® 64 and IA-32 Architectures Software Developer’s Manual, Volume 3A*.
  - The VMM should reflect the exception causing the VM exit to guest software in any of the following cases:
    - The value of bits 10:8 (interruption type) of the IDT-vectoring information field is anything other than 3 (hardware exception).
    - The value of bits 7:0 (vector) of the IDT-vectoring information field indicates a benign exception (1, 2, 3, 4, 5, 6, 7, 9, 16, 17, 18, or 19).
    - The value of bits 7:0 (vector) of the VM-exit interruption-information field indicates a benign exception.
    - The value of bits 7:0 of the IDT-vectoring information field indicates a contributory exception (0, 10, 11, 12, or 13) and the value of bits 7:0 of the VM-exit interruption-information field indicates a page fault (14).
  - If the value of bits 10:8 of the IDT-vectoring information field is 3 (hardware exception), the VMM should reflect a double-fault exception to guest software in any of the following cases:
    - The value of bits 7:0 of the IDT-vectoring information field and the value of bits 7:0 of the VM-exit interruption-information field each indicates a contributory exception.
    - The value of bits 7:0 of the IDT-vectoring information field indicates a page fault and the value of bits 7:0 of the VM-exit interruption-information field indicates either a contributory exception or a page fault.

A VMM can reflect a double-fault exception to guest software by setting the VM-entry interruption-information and VM-entry exception error-code fields as follows:

- Set bits 7:0 (vector) of the VM-entry interruption-information field to 8 (#DF).
- Set bits 10:8 (interruption type) of the VM-entry interruption-information field to 3 (hardware exception).
- Set bit 11 (deliver error code) of the VM-entry interruption-information field to 1.
- Clear bits 30:12 (reserved) of VM-entry interruption-information field.
- Set bit 31 (valid) of VM-entry interruption-information field.
- Set the VM-entry exception error-code field to zero.

## VIRTUAL-MACHINE MONITOR PROGRAMMING CONSIDERATIONS

- If the value of bits 10:8 of the IDT-vectoring information field is 3 (hardware exception) and the value of bits 7:0 is 8 (#DF), guest software would have encountered a triple fault. Event injection should not be used in this case. The VMM may choose to terminate the guest, or it might choose to enter the guest in the shutdown activity state.

### 27.7.1.2 Resuming Guest Software after Handling an Exception

If the VMM determines that a VM exit was caused by an exception due to a condition established by the VMM itself, it may choose to resume guest software after removing the condition. The approach for removing the condition may be specific to the VMM’s software architecture. This section describes how guest software may be resumed after removing the condition.

In general, the VMM can resume guest software simply by executing VMRESUME. The following items provide details of cases that may require special handling:

- If the “NMI exiting” VM-execution control is 0, bit 12 of the VM-exit interruption-information field indicates that the VM exit was due to a fault encountered during an execution of the IRET instruction that unblocked non-maskable interrupts (NMIs). In particular, it provides this indication if the following are both true:

- Bit 31 (valid) in the IDT-vectoring information field is 0.
- The value of bits 7:0 (vector) of the VM-exit interruption-information field is not 8 (the VM exit is not due to a double-fault exception).

If both are true and bit 12 of the VM-exit interruption-information field is 1, NMIs were blocked before guest software executed the IRET instruction that caused the fault that caused the VM exit. The VMM should set bit 3 (blocking by NMI) in the interruptibility-state field (using VMREAD and VMWRITE) before resuming guest software.

- If the “virtual NMIs” VM-execution control is 1, bit 12 of the VM-exit interruption-information field indicates that the VM exit was due to a fault encountered during an execution of the IRET instruction that removed virtual-NMI blocking. In particular, it provides this indication if the following are both true:

- Bit 31 (valid) in the IDT-vectoring information field is 0.
- The value of bits 7:0 (vector) of the VM-exit interruption-information field is not 8 (the VM exit is not due to a double-fault exception).

If both are true and bit 12 of the VM-exit interruption-information field is 1, there was virtual-NMI blocking before guest software executed the IRET instruction that caused the fault that caused the VM exit. The VMM should set bit 3 (blocking by NMI) in the interruptibility-state field (using VMREAD and VMWRITE) before resuming guest software.

- Bit 31 (valid) of the IDT-vectoring information field indicates, if set, that the exception causing the VM exit occurred while another event was being delivered to guest software. The VMM should ensure that the other event is delivered when

guest software is resumed. It can do so using the VM-entry event injection described in Section 23.5 and detailed in the following paragraphs:

- The VMM can copy (using VMREAD and VMWRITE) the contents of the IDT-vectoring information field (which is presumed valid) to the VM-entry interruption-information field (which, if valid, will cause the exception to be delivered as part of the next VM entry).
- The VMM should ensure that reserved bits 30:12 in the VM-entry interruption-information field are 0. In particular, the value of bit 12 in the IDT-vectoring information field is undefined after all VM exits. If this bit is copied as 1 into the VM-entry interruption-information field, the next VM entry will fail because the bit should be 0.
- If the “virtual NMIs” VM-execution control is 1 and the value of bits 10:8 (interruption type) in the IDT-vectoring information field is 2 (indicating NMI), the VM exit occurred during delivery of an NMI that had been injected as part of the previous VM entry. In this case, bit 3 (blocking by NMI) will be 1 in the interruptibility-state field in the VMCS. The VMM should clear this bit; otherwise, the next VM entry will fail (see Section 23.3.1.5).
- The VMM can also copy the contents of the IDT-vectoring error-code field to the VM-entry exception error-code field. This need not be done if bit 11 (error code valid) is clear in the IDT-vectoring information field.
- The VMM can also copy the contents of the VM-exit instruction-length field to the VM-entry instruction-length field. This need be done only if bits 10:8 (interruption type) in the IDT-vectoring information field indicate either software interrupt, privileged software exception, or software exception.

## 27.8 MULTI-PROCESSOR CONSIDERATIONS

The most common VMM design will be the symmetric VMM. This type of VMM runs the same VMM binary on all logical processors. Like a symmetric operating system, the symmetric VMM is written to ensure all critical data is updated by only one processor at a time, IO devices are accessed sequentially, and so forth. Asymmetric VMM designs are possible. For example, an asymmetric VMM may run its scheduler on one processor and run just enough of the VMM on other processors to allow the correct execution of guest VMs. The remainder of this section focuses on the multi-processor considerations for a symmetric VMM.

A symmetric VMM design does not preclude asymmetry in its operations. For example, a symmetric VMM can support asymmetric allocation of logical processor resources to guests. Multiple logical processors can be brought into a single guest environment to support an MP-aware guest OS. Because an active VMCS can not control more than one logical processor simultaneously, a symmetric VMM must make copies of its VMCS to control the VM allocated to support an MP-aware guest

## VIRTUAL-MACHINE MONITOR PROGRAMMING CONSIDERATIONS

OS. Care must be taken when accessing data structures shared between these VMCSs. See Section 27.8.4.

Although it may be easier to develop a VMM that assumes a fully-symmetric view of hardware capabilities (with all processors supporting the same processor feature sets, including the same revision of VMX), there are advantages in developing a VMM that comprehends different levels of VMX capability (reported by VMX capability MSRs). One possible advantage of such an approach could be that an existing software installation (VMM and guest software stack) could continue to run without requiring software upgrades to the VMM, when the software installation is upgraded to run on hardware with enhancements in the processor's VMX capabilities. Another advantage could be that a single software installation image, consisting of a VMM and guests, could be deployed to multiple hardware platforms with varying VMX capabilities. In such cases, the VMM could fall back to a common subset of VMX features supported by all VMX revisions, or choose to understand the asymmetry of the VMX capabilities and assign VMs accordingly.

This section outlines some of the considerations to keep in mind when developing an MP-aware VMM.

### 27.8.1 Initialization

Before enabling VMX, an MP-aware VMM must check to make sure that all processors in the system are compatible and support features required. This can be done by:

- Checking the CPUID on each logical processor to ensure VMX is supported and that the overall feature set of each logical processor is compatible.
- Checking VMCS revision identifiers on each logical processor.
- Checking each of the "allowed-1" or "allowed-0" fields of the VMX capability MSR's on each processor.

### 27.8.2 Moving a VMCS Between Processors

An MP-aware VMM is free to assign any logical processor to a VM. But for performance considerations, moving a guest VMCS to another logical processor is slower than resuming that guest VMCS on the same logical processor. Certain VMX performance features (such as caching of portions of the VMCS in the processor) are optimized for a guest VMCS that runs on the same logical processor.

The reasons are:

- To restart a guest on the same logical processor, a VMM can use VMRESUME. VMRESUME is expected to be faster than VMLAUNCH in general.
- To migrate a VMCS to another logical processor, a VMM must use the sequence of VMCLEAR, VMPTRLD and VMLAUNCH.
- Operations involving VMCLEAR can impact performance negatively. See Section 21.10.3.

A VMM scheduler should make an effort to schedule a guest VMCS to run on the logical processor where it last ran. Such a scheduler might also benefit from doing lazy VMCLEARs (that is: performing a VMCLEAR on a VMCS only when the scheduler knows the VMCS is being moved to a new logical processor). The remainder of this section describes the steps a VMM must take to move a VMCS from one processor to another.

A VMM must check the VMCS revision identifier in the VMX capability MSR IA32\_VMX\_BASIC to determine if the VMCS regions are identical between all logical processors. If the VMCS regions are identical (same revision ID) the following sequence can be used to move or copy the VMCS from one logical processor to another:

- Perform a VMCLEAR operation on the source logical processor. This ensures that all VMCS data that may be cached by the processor are flushed to memory.
- Copy the VMCS region from one memory location to another location. This is an optional step assuming the VMM wishes to relocate the VMCS or move the VMCS to another system.
- Perform a VMPTRLD of the physical address of VMCS region on the destination processor to establish its current VMCS pointer.

If the revision identifiers are different, each field must be copied to an intermediate structure using individual reads (VMREAD) from the source fields and writes (VMWRITE) to destination fields. Care must be taken on fields that are hard-wired to certain values on some processor implementations.

### 27.8.3 Paired Index-Data Registers

A VMM may need to virtualize hardware that is visible to software using paired index-data registers. Paired index-data register interfaces, such as those used in PCI (CF8, CFC), require special treatment in cases where a VM performing writes to these pairs can be moved during execution. In this case, the index (e.g. CF8) should be part of the virtualized state. If the VM is moved during execution, writes to the index should be redone so subsequent data reads/writes go to the right location.

### 27.8.4 External Data Structures

Certain fields in the VMCS point to external data structures (for example: the MSR bitmap, the I/O bitmaps). If a logical processor is in VMX non-root operation, none of the external structures referenced by that logical processor's current VMCS should be modified by any logical processor or DMA. Before updating one of these structures, the VMM must ensure that no logical processor whose current VMCS references the structure is in VMX non-root operation.

If a VMM uses multiple VMCS with each VMCS using separate external structures, and these structures must be kept synchronized, the VMM must apply the same care to updating these structures.

### 27.8.5 CPUID Emulation

CPUID reports information that is used by OS and applications to detect hardware features. It also provides multi-threading/multi-core configuration information. For example, MP-aware OSs rely on data reported by CPUID to discover the topology of logical processors in a platform (see Section 8.9, “Programming Considerations for Hardware Multi-Threading Capable Processors,” in the *Intel® 64 and IA-32 Architectures Software Developer’s Manual, Volume 3A*).

If a VMM is to support asymmetric allocation of logical processor resources to guest OSs that are MP aware, then the VMM must emulate CPUID for its guests. The emulation of CPUID by the VMM must ensure the guest’s view of CPUID leaves are consistent with the logical processor allocation committed by the VMM to each guest OS.

## 27.9 32-BIT AND 64-BIT GUEST ENVIRONMENTS

For the most part, extensions provided by VMX to support virtualization are orthogonal to the extensions provided by Intel 64 architecture. There are considerations that impact VMM designs. These are described in the following subsections.

### 27.9.1 Operating Modes of Guest Environments

For Intel 64 processors, VMX operation supports host and guest environments that run in IA-32e mode or without IA-32e mode. VMX operation also supports host and guest environments on IA-32 processors.

A VMM entering VMX operation while IA-32e mode is active is considered to be an IA-32e mode host. A VMM entering VMX operation while IA-32e mode is not activated or not available is referred to as a 32-bit VMM. The type of guest operations such VMMs support are summarized in Table 27-1.

**Table 27-1. Operating Modes for Host and Guest Environments**

| Capability      | Guest Operation in IA-32e mode | Guest Operation Not Requiring IA-32e Mode |
|-----------------|--------------------------------|-------------------------------------------|
| IA-32e mode VMM | Yes                            | Yes                                       |
| 32-bit VMM      | Not supported                  | Yes                                       |

A VM exit may occur to an IA-32e mode guest in either 64-bit sub-mode or compatibility sub-mode of IA-32e mode. VMMs may resume guests in either mode. The sub-mode in which an IA-32e mode guest resumes VMX non-root operation is determined by the attributes of the code segment which experienced the VM exit. If CS.L = 1, the guest is executing in 64-bit mode; if CS.L = 0, the guest is executing in compatibility mode (see Section 27.9.5).

Not all of an IA-32e mode VMM must run in 64-bit mode. While some parts of an IA-32e mode VMM must run in 64-bit mode, there are only a few restrictions preventing a VMM from executing in compatibility mode. The most notable restriction is that most VMX instructions cause exceptions when executed in compatibility mode.

## 27.9.2 Handling Widths of VMCS Fields

Individual VMCS control fields must be accessed using VMREAD or VMWRITE instructions. Outside of 64-Bit mode, VMREAD and VMWRITE operate on 32 bits of data. The widths of VMCS control fields may vary depending on whether a processor supports Intel 64 architecture.

Many VMCS fields are architected to extend transparently on processors supporting Intel 64 architecture (64 bits on processors that support Intel 64 architecture, 32 bits on processors that do not). Some VMCS fields are 64-bits wide regardless of whether the processor supports Intel 64 architecture or is in IA-32e mode.

### 27.9.2.1 Natural-Width VMCS Fields

Many VMCS fields operate using natural width. Such fields return (on reads) and set (on writes) 32-bits when operating in 32-bit mode and 64-bits when operating in 64-bit mode. For the most part, these fields return the naturally expected data widths. The "Guest RIP" field in the VMCS guest-state area is an example of this type of field.

### 27.9.2.2 64-Bit VMCS Fields

Unlike natural width fields, these fields are fixed to 64-bit width on all processors. When in 64-bit mode, reads of these fields return 64-bit wide data and writes to these fields write 64-bits. When outside of 64-bit mode, reads of these fields return the low 32-bits and writes to these fields write the low 32-bits and zero the upper 32-bits. Should a non-IA-32e mode host require access to the upper 32-bits of these fields, a separate VMCS encoding is used when issuing VMREAD/VMWRITE instructions.

The VMCS control field "MSR bitmap address" (which contains the physical address of a region of memory which specifies which MSR accesses should generate VM-exits) is an example of this type of field. Specifying encoding 00002004H to VMREAD returns the lower 32-bits to non-IA-32e mode hosts and returns 64-bits to 64-bit hosts. The separate encoding 00002005H returns only the upper 32-bits.

## 27.9.3 IA-32e Mode Hosts

An IA-32e mode host is required to support 64-bit guest environments. Because activating IA-32e mode currently requires that paging be disabled temporarily and VMX entry requires paging to be enabled, IA-32e mode must be enabled before entering

## VIRTUAL-MACHINE MONITOR PROGRAMMING CONSIDERATIONS

VMX operation. For this reason, it is not possible to toggle in and out of IA-32e mode in a VMM.

Section 27.5 describes the steps required to launch a VMM. An IA-32e mode host is also required to set the “host address-space size” VMCS VM-exit control to 1. The value of this control is then loaded in the IA32\_EFER.LME/LMA and CS.L bits on each VM exit. This establishes a 64-bit host environment as execution transfers to the VMM entry point. At a minimum, the entry point is required to be in a 64-bit code segment. Subsequently, the VMM can, if it chooses, switch to 32-bit compatibility mode on a code-segment basis (see Section 27.9.1). Note, however, that VMX instructions other than VMCALL are not supported in compatibility mode; they generate an invalid opcode exception if used.

The following VMCS controls determine the value of IA32\_EFER when a VM exit occurs: the “host address-space size” control (described above), the “load IA32\_EFER” VM-exit control, the “VM-exit MSR-load count,” and the “VM-exit MSR-load address” (see Section 24.3).

If the “load IA32\_EFER” VM-exit control is 1, the value of the LME and LMA bits in the IA32\_EFER field in the host-state area must be the value of the “host address-space size” VM-exit control.

The loading of IA32\_EFER.LME/LMA and CS.L bits established by the “host address-space size” control precede any loading of the IA32\_EFER MSR due from the VM-exit MSR-load area. If IA32\_EFER is specified in the VM-exit MSR-load area, the value of the LME bit in the load image of IA32\_EFER should match the setting of the “host address-space size” control. Otherwise the attempt to modify the LME bit (while paging is enabled) will lead to a VMX-abort. However, IA32\_EFER.LMA is always set by the processor to equal IA32\_EFER.LME & CRO.PG; the value specified for LMA in the load image of the IA32\_EFER MSR is ignored. For these and performance reasons, VMM writers may choose to not use the VM-exit/entry MSR-load/save areas for IA32\_EFER.

On a VMM teardown, VMX operation should be exited before deactivating IA-32e mode if the latter is required.

### 27.9.4 IA-32e Mode Guests

A 32-bit guest can be launched by either IA-32e-mode hosts or non-IA-32e-mode hosts. A 64-bit guests can only be launched by a IA-32e-mode host.

In addition to the steps outlined in Section 27.6, VMM writers need to:

- Set the “IA-32e-mode guest” VM-entry control to 1 in the VMCS to assure VM-entry (VMLAUNCH or VMRESUME) will establish a 64-bit (or 32-bit compatible) guest operating environment.
- Enable paging (CRO.PG) and PAE mode (CR4.PAE) to assure VM-entry to a 64-bit guest will succeed.

- Ensure that the host to be in IA-32e mode (the IA32\_EFER.LMA must be set to 1) and the setting of the VM-exit “host address-space size” control bit in the VMCS must also be set to 1.

If each of the above conditions holds true, then VM-entry will copy the value of the VM-entry “IA-32e-mode guest” control bit into the guests IA32\_EFER.LME bit, which will result in subsequent activation of IA-32e mode. If any of the above conditions is false, the VM-entry will fail and load state from the host-state area of the working VMCS as if a VM exit had occurred (see Section 23.7).

The following VMCS controls determine the value of IA32\_EFER on a VM entry: the “IA-32e-mode guest” VM-entry control (described above), the “load IA32\_EFER” VM-entry control, the “VM-entry MSR-load count,” and the “VM-entry MSR-load address” (see Section 23.4).

If the “load IA32\_EFER” VM-entry control is 1, the value of the LME and LMA bits in the IA32\_EFER field in the guest-state area must be the value of the “IA-32e-mode guest” VM-exit control. Otherwise, the VM entry fails.

The loading of IA32\_EFER.LME bit (described above) precedes any loading of the IA32\_EFER MSR from the VM-entry MSR-load area of the VMCS. If loading of IA32\_EFER is specified in the VM-entry MSR-load area, the value of the LME bit in the load image should be match the setting of the “IA-32e-mode guest” VM-entry control. Otherwise, the attempt to modify the LME bit (while paging is enabled) results in a failed VM entry. However, IA32\_EFER.LMA is always set by the processor to equal IA32\_EFER.LME & CRO.PG; the value specified for LMA in the load image of the IA32\_EFER MSR is ignored. For these and performance reasons, VMM writers may choose to not use the VM-exit/entry MSR-load/save areas for IA32\_EFER MSR.

Note that the VMM can control the processor’s architectural state when transferring control to a VM. VMM writers may choose to launch guests in protected mode and subsequently allow the guest to activate IA-32e mode or they may allow guests to toggle in and out of IA-32e mode. In this case, the VMM should require VM exit on accesses to the IA32\_EFER MSR to detect changes in the operating mode and modify the VM-entry “IA-32e-mode guest” control accordingly.

A VMM should save/restore the extended (full 64-bit) contents of the guest general-purpose registers, the new general-purpose registers (R8-R15) and the SIMD registers introduced in 64-bit mode should it need to modify these upon VM exit.

### 27.9.5 32-Bit Guests

To launch or resume a 32-bit guest, VMM writers can follow the steps outlined in Section 27.6, making sure that the “IA-32e-mode guest” VM-entry control bit is set to 0. Then the “IA-32e-mode guest” control bit is copied into the guest IA32\_EFER.LME bit, establishing IA32\_EFER.LMA as 0.

## 27.10 HANDLING MODEL SPECIFIC REGISTERS

Model specific registers (MSR) provide a wide range of functionality. They affect processor features, control the programming interfaces, or are used in conjunction with specific instructions. As part of processor virtualization, a VMM may wish to protect some or all MSR resources from direct guest access.

VMX operation provides the following features to virtualize processor MSRs.

### 27.10.1 Using VM-Execution Controls

Processor-based VM-execution controls provide two levels of support for handling guest access to processor MSRs using RDMSR and WRMSR:

- **MSR bitmaps:** In VMX implementations that support a 1-setting (see Appendix G) of the user-MSR-bitmaps execution control bit, MSR bitmaps can be used to provide flexibility in managing guest MSR accesses. The MSR-bitmap-address in the guest VMCS can be programmed by VMM to point to a bitmap region which specifies VM-exit behavior when reading and writing individual MSRs.

MSR bitmaps form a 4-KByte region in physical memory and are required to be aligned to a 4-KByte boundary. The first 1-KByte region manages read control of MSRs in the range 00000000H-00001FFFFH; the second 1-KByte region covers read control of MSR addresses in the range C0000000H-C0001FFFFH. The bitmaps for write control of these MSRs are located in the 2-KByte region immediately following the read control bitmaps. While the MSR bitmap address is part of VMCS, the MSR bitmaps themselves are not. This implies MSR bitmaps are not accessible through VMREAD and VMWRITE instructions but rather by using ordinary memory writes. Also, they are not specially cached by the processor and may be placed in normal cache-coherent memory by the VMM.

When MSR bitmap addresses are properly programmed and the use-MSR-bitmap control (see Section 21.6.2) is set, the processor consults the associated bit in the appropriate bitmap on guest MSR accesses to the corresponding MSR and causes a VM exit if the bit in the bitmap is set. Otherwise, the access is permitted to proceed. This level of protection may be utilized by VMMs to selectively allow guest access to some MSRs while virtualizing others.

- **Default MSR protection:** If the use-MSR-bitmap control is not set, an attempt by a guest to access any MSR causes a VM exit. This also occurs for any attempt to access an MSR outside the ranges identified above (even if the use-MSR-bitmap control is set).

VM exits due to guest MSR accesses may be identified by the VMM through VM-exit reason codes. The MSR-read exit reason implies guest software attempted to read an MSR protected either by default or through MSR bitmaps. The MSR-write exit reason implies guest software attempting to write a MSR protected through the VM-execution controls. Upon VM exits caused by MSR accesses, the VMM may virtualize the guest MSR access through emulation of RDMSR/WRMSR.

### 27.10.2 Using VM-Exit Controls for MSRs

If a VMM allows its guest to access MSRs directly, the VMM may need to store guest MSR values and load host MSR values for these MSRs on VM exits. This is especially true if the VMM uses the same MSRs while in VMX root operation.

A VMM can use the VM-exit MSR-store-address and the VM-exit MSR-store-count exit control fields (see Section 21.7.2) to manage how MSRs are stored on VM exits. The VM-exit MSR-store-address field contains the physical address (16-byte aligned) of the VM-exit MSR-store area (a table of entries with 16 bytes per entry). Each table entry specifies an MSR whose value needs to be stored on VM exits. The VM-exit MSR-store-count contains the number of entries in the table.

Similarly the VM-exit MSR-load-address and VM-exit MSR-load-count fields point to the location and size of the VM-exit MSR load area. The entries in the VM-exit MSR-load area contain the host expected values of specific MSRs when a VM exit occurs.

Upon VM-exit, bits 127:64 of each entry in the VM-exit MSR-store area is updated with the contents of the MSR indexed by bits 31:0. Also, bits 127:64 of each entry in the VM-exit MSR-load area is updated by loading with values from bits 127:64 the contents of the MSR indexed by bits 31:0.

### 27.10.3 Using VM-Entry Controls for MSRs

A VMM may require specific MSRs to be loaded explicitly on VM entries while launching or resuming guest execution. The VM-entry MSR-load-address and VM-entry MSR-load-count entry control fields determine how MSRs are loaded on VM-entries. The VM-entry MSR-load-address and count fields are similar in structure and function to the VM-exit MSR-load address and count fields, except the MSR loading is done on VM-entries.

### 27.10.4 Handling Special-Case MSRs and Instructions

A number of instructions make use of designated MSRs in their operation. The VMM may need to consider saving the states of those MSRs. Instructions that merit such consideration include SYSENTER/SYSEXIT, SYSCALL/SYSRET, SWAPGS.

#### 27.10.4.1 Handling IA32\_EFER MSR

The IA32\_EFER MSR includes bit fields that allow system software to enable processor features. For example: the SCE bit enables SYSCALL/SYSRET and the NXE bit enables the execute-disable bits in the paging-structure entries.

VMX provides hardware support to load the IA32\_EFER MSR on VMX transitions and to save it on VM exits. Because of this, VMM software need not use the RDMSR and WRMSR instruction to give the register different values during host and guest execution.

## VIRTUAL-MACHINE MONITOR PROGRAMMING CONSIDERATIONS

### 27.10.4.2 Handling the SYSENTER and SYSEXIT Instructions

The SYSENTER and SYSEXIT instructions use three dedicated MSRs (IA32\_SYSENTER\_CS, IA32\_SYSENTER\_ESP and IA32\_SYSENTER\_EIP) to manage fast system calls. These MSRs may be utilized by both the VMM and the guest OS to manage system calls in VMX root operation and VMX non-root operation respectively.

VM entries load these MSRs from fields in the guest-state area of the VMCS. VM exits save the values of these MSRs into those fields and loads the MSRs from fields in the host-state area.

### 27.10.4.3 Handling the SYSCALL and SYSRET Instructions

The SYSCALL/SYSRET instructions are similar to SYSENTER/SYSEXIT but are designed to operate within the context of a 64-bit flat code segment. They are available only in 64-bit mode and only when the SCE bit of the IA32\_EFER MSR is set. SYSCALL/SYSRET invocations can occur from either 32-bit compatibility mode application code or from 64-bit application code. Three related MSR registers (IA32\_STAR, IA32\_LSTAR, IA32\_FMASK) are used in conjunction with fast system calls/returns that use these instructions.

64-Bit hosts which make use of these instructions in the VMM environment will need to save the guest state of the above registers on VM exit, load the host state, and restore the guest state on VM entry. One possible approach is to use the VM-exit MSR-save and MSR-load areas and the VM-entry MSR-load area defined by controls in the VMCS. A disadvantage to this approach, however, is that the approach results in the unconditional saving, loading, and restoring of MSR registers on each VM exit or VM entry.

Depending on the design of the VMM, it is likely that many VM-exits will require no fast system call support but the VMM will be burdened with the additional overhead of saving and restoring MSRs if the VMM chooses to support fast system call uniformly. Further, even if the host intends to support fast system calls during a VM-exit, some of the MSR values (such as the setting of the SCE bit in IA32\_EFER) may not require modification as they may already be set to the appropriate value in the guest.

For performance reasons, a VMM may perform lazy save, load, and restore of these MSR values on certain VM exits when it is determined that this is acceptable. The lazy-save-load-restore operation can be carried out "manually" using RDMSR and WRMSR.

### 27.10.4.4 Handling the SWAPGS Instruction

The SWAPGS instruction is available only in 64-bit mode. It swaps the contents of two specific MSRs (IA32\_GSBASE and IA32\_KERNEL\_GSBASE). The IA32\_GSBASE MSR shadows the base address portion of the GS descriptor register; the IA32\_KERNEL\_GSBASE MSR holds the base address of the GS segment used by the kernel (typically it houses kernel structures). SWAPGS is intended for use with fast

system calls when in 64-bit mode to allow immediate access to kernel structures on transition to kernel mode.

Similar to SYSCALL/SYSRET, IA-32e mode hosts which use fast system calls may need to save, load, and restore these MSR registers on VM exit and VM entry using the guidelines discussed in previous paragraphs.

#### 27.10.4.5 Implementation Specific Behavior on Writing to Certain MSRs

As noted in Section 23.4 and Section 24.4, a processor may prevent writing to certain MSRs when loading guest states on VM entries or storing guest states on VM exits. This is done to ensure consistent operation. The subset and number of MSRs subject to restrictions are implementation specific. For initial VMX implementations, there are two MSRs: IA32 BIOS\_UPDT\_TRIG and IA32 BIOS\_SIGN\_ID (see Appendix B).

#### 27.10.5 Handling Accesses to Reserved MSR Addresses

Privileged software (either a VMM or a guest OS) can access a model specific register by specifying addresses in MSR address space. VMMs, however, must prevent a guest from accessing reserved MSR addresses in MSR address space.

Consult Appendix B for lists of supported MSRs and their usage. Use the MSR bitmap control to cause a VM exit when a guest attempts to access a reserved MSR address. The response to such a VM exit should be to reflect #GP(0) back to the guest.

### 27.11 HANDLING ACCESSES TO CONTROL REGISTERS

Bit fields in control registers (CR0, CR4) control various aspects of processor operation. The VMM must prevent guests from modifying bits in CR0 or CR4 that are reserved at the time the VMM is written.

Guest/host masks should be used by the VMM to cause VM exits when a guest attempts to modify reserved bits. Read shadows should be used to ensure that the guest always reads the reserved value (usually 0) for such bits. The VMM response to VM exits due to attempts from a guest to modify reserved bits should be to emulate the response which the processor would have normally produced (usually a #GP(0)).

### 27.12 PERFORMANCE CONSIDERATIONS

VMX provides hardware features that may be used for improving processor virtualization performance. VMMs must be designed to use this support properly. The basic idea behind most of these performance optimizations of the VMM is to reduce the number of VM exits while executing a guest VM.

## VIRTUAL-MACHINE MONITOR PROGRAMMING CONSIDERATIONS

This section lists ways that VMMs can take advantage of the performance enhancing features in VMX.

- **Read Access to Control Registers.** Analysis of common client workloads with common PC operating systems in a virtual machine shows a large number of VM-exits are caused by control register read accesses (particularly CRO). Reads of CRO and CR4 does not cause VM exits. Instead, they return values from the CRO/CR4 read-shadows configured by the VMM in the guest controlling-VMCS with the guest-expected values.
- **Write Access to Control Registers.** Most VMM designs require only certain bits of the control registers to be protected from direct guest access. Write access to CRO/CR4 registers can be reduced by defining the host-owned and guest-owned bits in them through the CRO/CR4 host/guest masks in the VMCS. CRO/CR4 write values by the guest are qualified with the mask bits. If they change only guest-owned bits, they are allowed without causing VM exits. Any write that cause changes to host-owned bits cause VM exits and need to be handled by the VMM.
- **Access Rights based Page Table protection.** For VMM that implement access-rights-based page table protection, the VMCS provides a CR3 target value list that can be consulted by the processor to determine if a VM exit is required. Loading of CR3 with a value matching an entry in the CR3 target-list are allowed to proceed without VM exits. The VMM can utilize the CR3 target-list to save page-table hierarchies whose state is previously verified by the VMM.
- **Page-fault handling.** Another common cause for a VM exit is due to page-faults induced by guest address remapping done through virtual memory virtualization. VMX provides page-fault error-code mask and match fields in the VMCS to filter VM exits due to page-faults based on their cause (reflected in the error-code).

### 27.13 USE OF THE VMX-PREEMPTION TIMER

The VMX-preemption timer allows VMM software to preempt guest VM execution after a specified amount of time. Typical VMX-preemption timer usage is to program the initial VM quantum into the timer, save the timer value on each successive VM-exit (using the VM-exit control "save preemption timer value") and run the VM until the timer expires.

In an alternative scenario, the VMM may use another timer (e.g. the TSC) to track the amount of time the VM has run while still using the VMX-preemption timer for VM preemption. In this scenario the VMM would not save the VMX-preemption timer on each VM-exit but instead would reload the VMX-preemption timer with initial VM quantum less the time the VM has already run. This scenario includes all the VM-entry and VM-exit latencies in the VM run time.

In both scenarios, on each successive VM-entry the VMX-preemption timer contains a smaller value until the VM quantum ends. If the VMX-preemption timer is loaded with a value smaller than the VM-entry latency then the VM will not execute any

## VIRTUAL-MACHINE MONITOR PROGRAMMING CONSIDERATIONS

instructions before the timer expires. The VMM must ensure the initial VM quantum is greater than the VM-entry latency; otherwise the VM will make no forward progress.

## VIRTUAL-MACHINE MONITOR PROGRAMMING CONSIDERATIONS

# CHAPTER 28

## VIRTUALIZATION OF SYSTEM RESOURCES

---

### 28.1 OVERVIEW

When a VMM is hosting multiple guest environments (VMs), it must monitor potential interactions between software components using the same system resources. These interactions can require the virtualization of resources. This chapter describes the virtualization of system resources. These include: debugging facilities, address translation, physical memory, and microcode update facilities.

### 28.2 VIRTUALIZATION SUPPORT FOR DEBUGGING FACILITIES

The Intel 64 and IA-32 debugging facilities (see Chapter 16) provide breakpoint instructions, exception conditions, register flags, debug registers, control registers and storage buffers for functions related to debugging system and application software. In VMX operation, a VMM can support debugging system and application software from within virtual machines if the VMM properly virtualizes debugging facilities. The following list describes features relevant to virtualizing these facilities.

- The VMM can program the exception-bitmap (see Section 21.6.3) to ensure it gets control on debug functions (like breakpoint exceptions occurring while executing guest code such as INT3 instructions). Normally, debug exceptions modify debug registers (such as DR6, DR7, IA32\_DEBUGCTL). However, if debug exceptions cause VM exits, exiting occurs before register modification.
- The VMM may utilize the VM-entry event injection facilities described in Section 23.5 to inject debug or breakpoint exceptions to the guest. See Section 28.2.1 for a more detailed discussion.
- The MOV-DR exiting control bit in the processor-based VM-execution control field (see Section 21.6.2) can be enabled by the VMM to cause VM exits on explicit guest access of various processor debug registers (for example, MOV to/from DR0-DR7). These exits would always occur on guest access of DR0-DR7 registers regardless of the values in CPL, DR4.DE or DR7.GD. Since all guest task switches cause VM exits, a VMM can control any indirect guest access or modification of debug registers during guest task switches.
- Guest software access to debug-related model-specific registers (such as IA32\_DEBUGCTL MSR) can be trapped by the VMM through MSR access control features (such as the MSR-bitmaps that are part of processor-based VM-execution controls). See Section 27.10 for details on MSR virtualization.

- Debug registers such as DR7 and the IA32\_DEBUGCTL MSR may be explicitly modified by the guest (through MOV-DR or WRMSR instructions) or modified implicitly by the processor as part of generating debug exceptions. The current values of DR7 and the IA32\_DEBUGCTL MSR are saved to guest-state area of VMCS on every VM exit. Pending debug exceptions are debug exceptions that are recognized by the processor but not yet delivered. See Section 23.6.3 for details on pending debug exceptions.
- DR7 and the IA32\_DEBUGCTL MSR are loaded from values in the guest-state area of the VMCS on every VM entry. This allows the VMM to properly virtualize debug registers when injecting debug exceptions to guest. Similarly, the RFLAGS<sup>1</sup> register is loaded on every VM entry (or pushed to stack if injecting a virtual event) from guest-state area of the VMCS. Pending debug exceptions are also loaded from guest-state area of VMCS so that they may be delivered after VM entry is completed.

### 28.2.1 Debug Exceptions

If a VMM emulates a guest instruction that would encounter a debug trap (single step or data or I/O breakpoint), it should cause that trap to be delivered. The VMM should not inject the debug exception using VM-entry event injection, but should set the appropriate bits in the pending debug exceptions field. This method will give the trap the right priority with respect to other events. (If the exception bitmap was programmed to cause VM exits on debug exceptions, the debug trap will cause a VM exit. At this point, the trap can be injected during VM entry with the proper priority.)

There is a valid pending debug exception if the BS bit (see Table 21-4) is set, regardless of the values of RFLAGS.TF or IA32\_DEBUGCTL.BTF. The values of these bits do not impact the delivery of pending debug exceptions.

VMMs should exercise care when emulating a guest write (attempted using WRMSR) to IA32\_DEBUGCTL to modify BTF if this is occurring with RFLAGS.TF = 1 and after a MOV SS or POP SS instruction (for example: while debug exceptions are blocked). Note the following:

- Normally, if WRMSR clears BTF while RFLAGS.TF = 1 and with debug exceptions blocked, a single-step trap will occur after WRMSR. A VMM emulating such an instruction should set the BS bit (see Table 21-4) in the pending debug exceptions field before VM entry.
- Normally, if WRMSR sets BTF while RFLAGS.TF = 1 and with debug exceptions blocked, neither a single-step trap nor a taken-branch trap can occur after WRMSR. A VMM emulating such an instruction should clear the BS bit (see Table 21-4) in the pending debug exceptions field before VM entry.

---

1. This chapter uses the notation RAX, RIP, RSP, RFLAGS, etc. for processor registers because most processors that support VMX operation also support Intel 64 architecture. For processors that do not support Intel 64 architecture, this notation refers to the 32-bit forms of those registers (EAX, EIP, ESP, EFLAGS, etc.).

## 28.3 MEMORY VIRTUALIZATION

VMMs must control physical memory to ensure VM isolation and to remap guest physical addresses in host physical address space for virtualization. Memory virtualization allows the VMM to enforce control of physical memory and yet support guest OSs' expectation to manage memory address translation.

### 28.3.1 Processor Operating Modes & Memory Virtualization

Memory virtualization is required to support guest execution in various processor operating modes. This includes: protected mode with paging, protected mode with no paging, real-mode and any other transient execution modes. VMX allows guest operation in protected-mode with paging enabled and in virtual-8086 mode (with paging enabled) to support guest real-mode execution. Guest execution in transient operating modes (such as in real mode with one or more segment limits greater than 64-KByte) must be emulated by the VMM.

Since VMX operation requires processor execution in protected mode with paging (through CR0 and CR4 fixed bits), the VMM may utilize paging structures to support memory virtualization. To support guest real-mode execution, the VMM may establish a simple flat page table for guest linear to host physical address mapping. Memory virtualization algorithms may also need to capture other guest operating conditions (such as guest performing A20M# address masking) to map the resulting 20-bit effective guest physical addresses.

### 28.3.2 Guest & Host Physical Address Spaces

Memory virtualization provides guest software with contiguous guest physical address space starting zero and extending to the maximum address supported by the guest virtual processor's physical address width. The VMM utilizes guest physical to host physical address mapping to locate all or portions of the guest physical address space in host memory. The VMM is responsible for the policies and algorithms for this mapping which may take into account the host system physical memory map and the virtualized physical memory map exposed to a guest by the VMM. The memory virtualization algorithm needs to accommodate various guest memory uses (such as: accessing DRAM, accessing memory-mapped registers of virtual devices or core logic functions and so forth). For example:

- To support guest DRAM access, the VMM needs to map DRAM-backed guest physical addresses to host-DRAM regions. The VMM also requires the guest to host memory mapping to be at page granularity.
- Virtual devices (I/O devices or platform core logic) emulated by the VMM may claim specific regions in the guest physical address space to locate memory-mapped registers. Guest access to these virtual registers may be configured to cause page-fault induced VM-exits by marking these regions as always not

present. The VMM may handle these VM exits by invoking appropriate virtual device emulation code.

### 28.3.3 Virtualizing Virtual Memory by Brute Force

VMX provides the hardware features required to fully virtualize guest virtual memory accesses. VMX allows the VMM to trap guest accesses to the PAT (Page Attribute Table) MSR and the MTRR (Memory Type Range Registers). This control allows the VMM to virtualize the specific memory type of a guest memory. The VMM may control caching by controlling the guest CR0.CRD and CR0.NW bits, as well as by trapping guest execution of the INVD instruction. The VMM can trap guest CR3 loads and stores, and it may trap guest execution of INVLPG.

Because a VMM must retain control of physical memory, it must also retain control over the processor's address-translation mechanisms. Specifically, this means that only the VMM can access CR3 (which contains the base of the page directory) and can execute INVLPG (the only other instruction that directly manipulates the TLB).

At the same time that the VMM controls address translation, a guest operating system will also expect to perform normal memory management functions. It will access CR3, execute INVLPG, and modify (what it believes to be) page directories and page tables. Virtualization of address translation must tolerate and support guest attempts to control address translation.

A simple-minded way to do this would be to ensure that all guest attempts to access address-translation hardware trap to the VMM where such operations can be properly emulated. It must ensure that accesses to page directories and page tables also get trapped. This may be done by protecting these in-memory structures with conventional page-based protection. The VMM can do this because it can locate the page directory because its base address is in CR3 and the VMM receives control on any change to CR3; it can locate the page tables because their base addresses are in the page directory.

Such a straightforward approach is not necessarily desirable. Protection of the in-memory translation structures may be cumbersome. The VMM may maintain these structures with different values (e.g., different page base addresses) than guest software. This means that there must be traps on guest attempt to read these structures and that the VMM must maintain, in auxiliary data structures, the values to return to these reads. There must also be traps on modifications to these structures even if the translations they effect are never used. All this implies considerable overhead that should be avoided.

### 28.3.4 Alternate Approach to Memory Virtualization

Guest software is allowed to freely modify the guest page-table hierarchy without causing traps to the VMM. Because of this, the active page-table hierarchy might not always be consistent with the guest hierarchy. Any potential problems arising from

inconsistencies can be solved using techniques analogous to those used by the processor and its TLB.

This section describes an alternative approach that allows guest software to freely access page directories and page tables. Traps occur on CR3 accesses and executions of INVLPG. They also occur when necessary to ensure that guest modifications to the translation structures actually take effect. The software mechanisms to support this approach are collectively called virtual TLB. This is because they emulate the functionality of the processor's physical translation look-aside buffer (TLB).

The basic idea behind the virtual TLB is similar to that behind the processor TLB. While the page-table hierarchy defines the relationship between physical to linear address, it does not directly control the address translation of each memory access. Instead, translation is controlled by the TLB, which is occasionally filled by the processor with translations derived from the page-table hierarchy. With a virtual TLB, the page-table hierarchy established by guest software (specifically, the guest operating system) does not control translation, either directly or indirectly. Instead, translation is controlled by the processor (through its TLB) and by the VMM (through a page-table hierarchy that it maintains).

Specifically, the VMM maintains an alternative page-table hierarchy that effectively caches translations derived from the hierarchy maintained by guest software. The remainder of this document refers to the former as the active page-table hierarchy (because it is referenced by CR3 and may be used by the processor to load its TLB) and the latter as the guest page-table hierarchy (because it is maintained by guest software). The entries in the active hierarchy may resemble the corresponding entries in the guest hierarchy in some ways and may differ in others.

Guest software is allowed to freely modify the guest page-table hierarchy without causing VM exits to the VMM. Because of this, the active page-table hierarchy might not always be consistent with the guest hierarchy. Any potential problems arising from any inconsistencies can be solved using techniques analogous to those used by the processor and its TLB. Note the following:

- Suppose the guest page-table hierarchy allows more access than active hierarchy (for example: there is a translation for a linear address in the guest hierarchy but not in the active hierarchy); this is analogous to a situation in which the TLB allows less access than the page-table hierarchy. If an access occurs that would be allowed by the guest hierarchy but not the active one, a page fault occurs; this is analogous to a TLB miss. The VMM gains control (as it handles all page faults) and can update the active page-table hierarchy appropriately; this corresponds to a TLB fill.
- Suppose the guest page-table hierarchy allows less access than the active hierarchy; this is analogous to a situation in which the TLB allows more access than the page-table hierarchy. This situation can occur only if the guest operating system has modified a page-table entry to reduce access (for example: by marking it not-present). Because the older, more permissive translation may have been cached in the TLB, the processor is architecturally permitted to use the older translation and allow more access. Thus, the VMM may (through the active page-table hierarchy) also allow greater access. For the new, less permissive

translation to take effect, guest software should flush any older translations from the TLB either by executing INVLPG or by loading CR3. Because both these operations will cause a trap to the VMM, the VMM will gain control and can remove from the active page-table hierarchy the translations indicated by guest software (the translation of a specific linear address for INVLPG or all translations for a load of CR3).

As noted previously, the processor reads the page-table hierarchy to cache translations in the TLB. It also writes to the hierarchy to main the accessed (A) and dirty (D) bits in the PDEs and PTEs. The virtual TLB emulates this behavior as follows:

- When a page is accessed by guest software, the A bit in the corresponding PTE (or PDE for a 4-MByte page) in the active page-table hierarchy will be set by the processor (the same is true for PDEs when active page tables are accessed by the processor). For guest software to operate properly, the VMM should update the A bit in the guest entry at this time. It can do this reliably if it keeps the active PTE (or PDE) marked not-present until it has set the A bit in the guest entry.
- When a page is written by guest software, the D bit in the corresponding PTE (or PDE for a 4-MByte page) in the active page-table hierarchy will be set by the processor. For guest software to operate properly, the VMM should update the D bit in the guest entry at this time. It can do this reliably if it keeps the active PTE (or PDE) marked read-only until it has set the D bit in the guest entry. This solution is valid for guest software running at privilege level 3; support for more privileged guest software is described in Section 28.3.5.

### 28.3.5 Details of Virtual TLB Operation

This section describes in more detail how a VMM could support a virtual TLB. It explains how an active page-table hierarchy is initialized and how it is maintained in response to page faults, uses of INVLPG, and accesses to CR3. The mechanisms described here are the minimum necessary. They may not result in the best performance.

Figure 28-1. Virtual TLB Scheme

As noted above, the VMM maintains an active page-table hierarchy for each virtual machine that it supports. It also maintains, for each machine, values that the machine expects for control registers CR0, CR2, CR3, and CR4 (they control address translation). These values are called the guest control registers.

In general, the VMM selects the physical-address space that is allocated to guest software. The term guest address refers to an address installed by guest software in the guest CR3, in a guest PDE (as a page table base address or a page base address), or in a guest PTE (as a page base address). While guest software considers these to be specific physical addresses, the VMM may map them differently.

### 28.3.5.1 Initialization of Virtual TLB

To enable the Virtual TLB scheme, the VMCS must be set up to trigger VM exits on:

- All writes to CR3 (the CR3-target count should be 0) or the paging-mode bits in CR0 and CR4 (using the CR0 and CR4 guest/host masks)
- Page-fault (#PF) exceptions
- Execution of INVLPG

## VIRTUALIZATION OF SYSTEM RESOURCES

When guest software first enables paging, the VMM creates an aligned 4-KByte active page directory that is invalid (all entries marked not-present). This invalid directory is analogous to an empty TLB.

### 28.3.5.2 Response to Page Faults

Page faults can occur for a variety of reasons. In some cases, the page fault alerts the VMM to an inconsistency between the active and guest page-table hierarchy. In such cases, the VMM can update the former and re-execute the faulting instruction. In other cases, the hierarchies are already consistent and the fault should be handled by the guest operating system. The VMM can detect this and use an established mechanism for raising a page fault to guest software.

The VMM can handle a page fault by following these steps (The steps below assume the guest is operating in a paging mode without PAE. Analogous steps to handle address translation using PAE or four-level paging mechanisms can be derived by VMM developers according to the paging behavior defined in Chapter 3 of the *Intel® 64 and IA-32 Architectures Software Developer's Manual, Volume 3A*):

1. First consult the active PDE, which can be located using the upper 10 bits of the faulting address and the current value of CR3. The active PDE is the source of the fault if it is marked not present or if its R/W bit and U/S bits are inconsistent with the attempted guest access (the guest privilege level and the values of CRO.WP and CR4.SMEP should also be taken into account).
2. If the active PDE is the source of the fault, consult the corresponding guest PDE using the same 10 bits from the faulting address and the physical address that corresponds to the guest address in the guest CR3. If the guest PDE would cause a page fault (for example: it is marked not present), then raise a page fault to the guest operating system.

The following steps assume that the guest PDE would not have caused a page fault.

3. If the active PDE is the source of the fault and the guest PDE contains, as page-table base address (if PS = 0) or page base address (PS = 1), a guest address that the VMM has chosen not to support; then raise a machine check (or some other abort) to the guest operating system.

The following steps assume that the guest address in the guest PDE is supported for the virtual machine.

4. If the active PDE is marked not-present, then set the active PDE to correspond to guest PDE as follows:
  - a. If the active PDE contains a page-table base address (if PS = 0), then allocate an aligned 4-KByte active page table marked completely invalid and set the page-table base address in the active PDE to be the physical address of the newly allocated page table.

- b. If the active PDE contains a page base address (if PS = 1), then set the page base address in the active PDE to be the physical page base address that corresponds to the guest address in the guest PDE.
- c. Set the P, U/S, and PS bits in the active PDE to be identical to those in the guest PDE.
- d. Set the PWT, PCD, and G bits according to the policy of the VMM.
- e. Set A = 1 in the guest PDE.
- f. If D = 1 in the guest PDE or PS = 0 (meaning that this PDE refers to a page table), then set the R/W bit in the active PDE as in the guest PDE.
- g. If D = 0 in the guest PDE, PS = 1 (this is a 4-MByte page), and the attempted access is a write; then set R/W in the active PDE as in the guest PDE and set D = 1 in the guest PDE.
- h. If D = 0 in the guest PDE, PS = 1, and the attempted access is not a write; then set R/W = 0 in the active PDE.
- i. After modifying the active PDE, re-execute the faulting instruction.

The remaining steps assume that the active PDE is already marked present.

- 5. If the active PDE is the source of the fault, the active PDE refers to a 4-MByte page (PS = 1), the attempted access is a write; D = 0 in the guest PDE, and the active PDE has caused a fault solely because it has R/W = 0; then set R/W in the active PDE as in the guest PDE; set D = 1 in the guest PDE, and re-execute the faulting instruction.
- 6. If the active PDE is the source of the fault and none of the above cases apply, then raise a page fault of the guest operating system.

The remaining steps assume that the source of the original page fault is not the active PDE.

#### NOTE

It is possible that the active PDE might be causing a fault even though the guest PDE would not. However, this can happen only if the guest operating system increased access in the guest PDE and did not take action to ensure that older translations were flushed from the TLB. Such translations might have caused a page fault if the guest software were running on bare hardware.

- 7. If the active PDE refers to a 4-MByte page (PS = 1) but is not the source of the fault, then the fault resulted from an inconsistency between the active page-table hierarchy and the processor's TLB. Since the transition to the VMM caused an address-space change and flushed the processor's TLB, the VMM can simply re-execute the faulting instruction.

The remaining steps assume that PS = 0 in the active and guest PDEs.

## VIRTUALIZATION OF SYSTEM RESOURCES

8. Consult the active PTE, which can be located using the next 10 bits of the faulting address (bits 21–12) and the physical page-table base address in the active PDE. The active PTE is the source of the fault if it is marked not-present or if its R/W bit and U/S bits are inconsistent with the attempted guest access (the guest privilege level and the values of CRO.WP and CR4.SMEP should also be taken into account).
9. If the active PTE is not the source of the fault, then the fault has resulted from an inconsistency between the active page-table hierarchy and the processor's TLB. Since the transition to the VMM caused an address-space change and flushed the processor's TLB, the VMM simply re-executes the faulting instruction.

The remaining steps assume that the active PTE is the source of the fault.

10. Consult the corresponding guest PTE using the same 10 bits from the faulting address and the physical address that correspond to the guest page-table base address in the guest PDE. If the guest PTE would cause a page fault (it is marked not-present), then raise a page fault to the guest operating system.

The following steps assume that the guest PTE would not have caused a page fault.

11. If the guest PTE contains, as page base address, a physical address that is not valid for the virtual machine being supported, then raise a machine check (or some other abort) to the guest operating system.

The following steps assume that the address in the guest PTE is valid for the virtual machine.

12. If the active PTE is marked not-present, then set the active PTE to correspond to guest PTE:

- a. Set the page base address in the active PTE to be the physical address that corresponds to the guest page base address in the guest PTE.
- b. Set the P, U/S, and PS bits in the active PTE to be identical to those in the guest PTE.
- c. Set the PWT, PCD, and G bits according to the policy of the VMM.
- d. Set A = 1 in the guest PTE.
- e. If D = 1 in the guest PTE, then set the R/W bit in the active PTE as in the guest PTE.
- f. If D = 0 in the guest PTE and the attempted access is a write, then set R/W in the active PTE as in the guest PTE and set D = 1 in the guest PTE.
- g. If D = 0 in the guest PTE and the attempted access is not a write, then set R/W = 0 in the active PTE.
- h. After modifying the active PTE, re-execute the faulting instruction.

The remaining steps assume that the active PTE is already marked present.

13. If the attempted access is a write, D = 0 (not dirty) in the guest PTE and the active PTE has caused a fault solely because it has R/W = 0 (read-only); then set

R/W in the active PTE as in the guest PTE, set D = 1 in the guest PTE and re-execute the faulting instruction.

14. If none of the above cases apply, then raise a page fault of the guest operating system.

#### 28.3.5.3 Response to Uses of INVLPG

Operating-systems can use INVLPG to flush entries from the TLB. This instruction takes a linear address as an operand and software expects any cached translations for the address to be flushed. A VMM should set the processor-based VM-execution control “INVLPG exiting” to 1 so that any attempts by a privileged guest to execute INVLPG will trap to the VMM. The VMM can then modify the active page-table hierarchy to emulate the desired effect of the INVLPG.

The following steps are performed. Note that these steps are performed only if the guest invocation of INVLPG would not fault and only if the guest software is running at privilege level 0:

1. Locate the relevant active PDE using the upper 10 bits of the operand address and the current value of CR3. If the PDE refers to a 4-MByte page (PS = 1), then set P = 0 in the PDE.
2. If the PDE is marked present and refers to a page table (PS = 0), locate the relevant active PTE using the next 10 bits of the operand address (bits 21–12) and the page-table base address in the PDE. Set P = 0 in the PTE. Examine all PTEs in the page table; if they are now all marked not-present, de-allocate the page table and set P = 0 in the PDE (this step may be optional).

#### 28.3.5.4 Response to CR3 Writes

A guest operating system may attempt to write to CR3. Any write to CR3 implies a TLB flush and a possible page table change. The following steps are performed:

1. The VMM notes the new CR3 value (used later to walk guest page tables) and emulates the write.
2. The VMM allocates a new PD page, with all invalid entries.
3. The VMM sets actual processor CR3 register to point to the new PD page.

The VMM may, at this point, speculatively fill in VTLB mappings for performance reasons.

### 28.4 MICROCODE UPDATE FACILITY

The microcode code update facility may be invoked at various points during the operation of a platform. Typically, the BIOS invokes the facility on all processors during the BIOS boot process. This is sufficient to boot the BIOS and operating system. As a

microcode update more current than the system BIOS may be available, system software should provide another mechanism for invoking the microcode update facility. The implications of the microcode update mechanism on the design of the VMM are described in this section.

**NOTE**

Microcode updates must not be performed during VMX non-root operation. Updates performed in VMX non-root operation may result in unpredictable system behavior.

#### **28.4.1 Early Load of Microcode Updates**

The microcode update facility may be invoked early in the VMM or guest OS boot process. Loading the microcode update early provides the opportunity to correct errata affecting the boot process but the technique generally requires a reboot of the software.

A microcode update may be loaded from the OS or VMM image loader. Typically, such image loaders do not run on every logical processor, so this method effects only one logical processor. Later in the VMM or OS boot process, after bringing all application processors on-line, the VMM or OS needs to invoke the microcode update facility for all application processors.

Depending on the order of the VMM and the guest OS boot, the microcode update facility may be invoked by the VMM or the guest OS. For example, if the guest OS boots first and then loads the VMM, the guest OS may invoke the microcode update facility on all the logical processors. If a VMM boots before its guests, then the VMM may invoke the microcode update facility during its boot process. In both cases, the VMM or OS should invoke the microcode update facilities soon after performing the multiprocessor startup.

In the early load scenario, microcode updates may be contained in the VMM or OS image or, the VMM or OS may manage a separate database or file of microcode updates. Maintaining a separate microcode update image database has the advantage of reducing the number of required VMM or OS releases as a result of microcode update releases.

#### **28.4.2 Late Load of Microcode Updates**

A microcode update may be loaded during normal system operation. This allows system software to activate the microcode update at anytime without requiring a system reboot. This scenario does not allow the microcode update to correct errata which affect the processor's boot process but does allow high-availability systems to activate microcode updates without interrupting the availability of the system. In this late load scenario, either the VMM or a designated guest may load the microcode update. If the guest is loading the microcode update, the VMM must make sure that

the entire guest memory buffer (which contains the microcode update image) will not cause a page fault when accessed.

If the VMM loads the microcode update, then the VMM must have access to the current set of microcode updates. These updates could be part of the VMM image or could be contained in a separate microcode update image database (for example: a database file on disk or in memory). Again, maintaining a separate microcode update image database has the advantage of reducing the number of required VMM or OS releases as a result of microcode update releases.

The VMM may wish to prevent a guest from loading a microcode update or may wish to support the microcode update requested by a guest using emulation (without actually loading the microcode update). To prevent microcode update loading, the VMM may return a microcode update signature value greater than the value of IA32 BIOS SIGN\_ID MSR. A well behaved guest will not attempt to load an older microcode update. The VMM may also drop the guest attempts to write to IA32 BIOS UPDT TRIG MSR, preventing the guest from loading any microcode updates. Later, when the guest queries IA32 BIOS SIGN\_ID MSR, the VMM could emulate the microcode update signature that the guest expects.

In general, loading a microcode update later will limit guest software's visibility of features that may be enhanced by a microcode update.

## VIRTUALIZATION OF SYSTEM RESOURCES

# CHAPTER 29

## HANDLING BOUNDARY CONDITIONS IN A VIRTUAL MACHINE MONITOR

---

### 29.1 OVERVIEW

This chapter describes what a VMM must consider when handling exceptions, interrupts, error conditions, and transitions between activity states.

### 29.2 INTERRUPT HANDLING IN VMX OPERATION

The following bullets summarize VMX support for handling interrupts:

- **Control of processor exceptions.** The VMM can get control on specific guest exceptions through the exception-bitmap in the guest controlling VMCS. The exception bitmap is a 32-bit field that allows the VMM to specify processor behavior on specific exceptions (including traps, faults, and aborts). Setting a specific bit in the exception bitmap implies VM exits will be generated when the corresponding exception occurs. Any exceptions that are programmed not to cause VM exits are delivered directly to the guest through the guest IDT. The exception bitmap also controls execution of relevant instructions such as BOUND, INTO and INT3. VM exits on page-faults are treated in such a way the page-fault error code is qualified through the page-fault-error-code mask and match fields in the VMCS.
- **Control over triple faults.** If a fault occurs while attempting to call a double-fault handler in the guest and that fault is not configured to cause a VM exit in the exception bitmap, the resulting triple fault causes a VM exit.
- **Control of external interrupts.** VMX allows both host and guest control of external interrupts through the “external-interrupt exiting” VM execution control. If the control is 0, external-interrupts do not cause VM exits and the interrupt delivery is masked by the guest programmed RFLAGS.IF value.<sup>1</sup> If the control is 1, external-interrupts causes VM exits and are not masked by RFLAGS.IF. The VMM can identify VM exits due to external interrupts by checking the exit reason for an “external interrupt” (value = 1).

---

1. This chapter uses the notation RAX, RIP, RSP, RFLAGS, etc. for processor registers because most processors that support VMX operation also support Intel 64 architecture. For processors that do not support Intel 64 architecture, this notation refers to the 32-bit forms of those registers (EAX, EIP, ESP, EFLAGS, etc.).

## HANDLING BOUNDARY CONDITIONS IN A VIRTUAL MACHINE MONITOR

- **Control of other events.** There is a pin-based VM-execution control that controls system behavior (exit or no-exit) for NMI events. Most VMM usages will need handling of NMI external events in the VMM and hence will specify host control of these events.

Some processors also support a pin-based VM-execution control called “virtual NMIs.” When this control is set, NMIs cause VM exits, but the processor tracks guest readiness for virtual NMIs. This control interacts with the “NMI-window exiting” VM-execution control (see below).

INIT and SIPI events always cause VM exits.

- **Acknowledge interrupt on exit.** The “acknowledge interrupt on exit” VM-exit control in the controlling VMCS controls processor behavior for external interrupt acknowledgement. If the control is 1, the processor acknowledges the interrupt controller to acquire the interrupt vector upon VM exit, and stores the vector in the VM-exit interruption-information field. If the control is 0, the external interrupt is not acknowledged during VM exit. Since RFLAGS.IF is automatically cleared on VM exits due to external interrupts, VMM re-enabling of interrupts (setting RFLAGS.IF = 1) initiates the external interrupt acknowledgement and vectoring of the external interrupt through the monitor/host IDT.
- **Event-masking Support.** VMX captures the masking conditions of specific events while in VMX non-root operation through the interruptibility-state field in the guest-state area of the VMCS.

This feature allows proper virtualization of various interrupt blocking states, such as: (a) blocking of external interrupts for the instruction following STI; (b) blocking of interrupts for the instruction following a MOV-SS or POP-SS instruction; (c) SMI blocking of subsequent SMIs until the next execution of RSM; and (d) NMI/SMI blocking of NMIs until the next execution of IRET or RSM.

INIT and SIPI events are treated specially. INIT assertions are always blocked in VMX root operation and while in SMM, and unblocked otherwise. SIPI events are always blocked in VMX root operation.

The interruptibility state is loaded from the VMCS guest-state area on every VM entry and saved into the VMCS on every VM exit.

- **Event injection.** VMX operation allows injecting interruptions to a guest virtual machine through the use of VM-entry interrupt-information field in VMCS. Injectable interruptions include external interrupts, NMI, processor exceptions, software generated interrupts, and software traps. If the interrupt-information field indicates a valid interrupt, exception or trap event upon the next VM entry; the processor will use the information in the field to vector a virtual interruption through the guest IDT after all guest state and MSRs are loaded. Delivery through the guest IDT emulates vectoring in non-VMX operation by doing the normal privilege checks and pushing appropriate entries to the guest stack (entries may include RFLAGS, EIP and exception error code). A VMM with host control of NMI and external interrupts can use the event-injection facility to forward virtual interruptions to various guest virtual machines.

- **Interrupt-window exiting.** When set to 1, the “interrupt-window exiting” VM-execution control (Section 21.6.2) causes VM exits when guest RFLAGS.IF is 1 and no other conditions block external interrupts. A VM exit occurs at the beginning of any instruction at which RFLAGS.IF = 1 and on which the interruptibility state of the guest would allow delivery of an interrupt. For example: when the guest executes an STI instruction, RFLAGS = 1, and if at the completion of next instruction the interruptibility state masking due to STI is removed; a VM exit occurs if the “interrupt-window exiting” VM-execution control is 1. This feature allows a VMM to queue a virtual interrupt to the guest when the guest is not in an interruptible state. The VMM can set the “interrupt-window exiting” VM-execution control for the guest and depend on a VM exit to know when the guest becomes interruptible (and, therefore, when it can inject a virtual interrupt). The VMM can detect such VM exits by checking for the basic exit reason “interrupt-window” (value = 7). If this feature is not used, the VMM will need to poll and check the interruptibility state of the guest to deliver virtual interrupts.
- **NMI-window exiting.** If the “virtual NMIs” VM-execution is set, the processor tracks virtual-NMI blocking. The “NMI-window exiting” VM-execution control (Section 21.6.2) causes VM exits when there is no virtual-NMI blocking. For example, after execution of the IRET instruction, a VM exit occurs if the “NMI-window exiting” VM-execution control is 1. This feature allows a VMM to queue a virtual NMI to a guest when the guest is not ready to receive NMIs. The VMM can set the “NMI-window exiting” VM-execution control for the guest and depend on a VM exit to know when the guest becomes ready for NMIs (and, therefore, when it can inject a virtual NMI). The VMM can detect such VM exits by checking for the basic exit reason “NMI window” (value = 8). If this feature is not used, the VMM will need to poll and check the interruptibility state of the guest to deliver virtual NMIs.
- **VM-exit information.** The VM-exit information fields provide details on VM exits due to exceptions and interrupts. This information is provided through the exit-qualification, VM-exit-interruption-information, instruction-length and interruption-error-code fields. Also, for VM exits that occur in the course of vectoring through the guest IDT, information about the event that was being vectored through the guest IDT is provided in the IDT-vectoring-information and IDT-vectoring-error-code fields. These information fields allow the VMM to identify the exception cause and to handle it properly.

## 29.3 EXTERNAL INTERRUPT VIRTUALIZATION

VMX operation allows both host and guest control of external interrupts. While guest control of external interrupts might be suitable for partitioned usages (different CPU cores/threads and I/O devices partitioned to independent virtual machines), most VMMs built upon VMX are expected to utilize host control of external interrupts. The rest of this section describes a general host-controlled interrupt virtualization architecture for standard PC platforms through the use of VMX supported features.

## HANDLING BOUNDARY CONDITIONS IN A VIRTUAL MACHINE MONITOR

With host control of external interrupts, the VMM (or the host OS in a hosted VMM model) manages the physical interrupt controllers in the platform and the interrupts generated through them. The VMM exposes software-emulated virtual interrupt controller devices (such as PIC and APIC) to each guest virtual machine instance.

### 29.3.1 Virtualization of Interrupt Vector Space

The Intel 64 and IA-32 architectures use 8-bit vectors of which 244 (20H – FFH) are available for external interrupts. Vectors are used to select the appropriate entry in the interrupt descriptor table (IDT). VMX operation allows each guest to control its own IDT. Host vectors refer to vectors delivered by the platform to the processor during the interrupt acknowledgement cycle. Guest vectors refer to vectors programmed by a guest to select an entry in its guest IDT. Depending on the I/O resource management models supported by the VMM design, the guest vector space may or may not overlap with the underlying host vector space.

- **Interrupts from virtual devices:** Guest vector numbers for virtual interrupts delivered to guests on behalf of emulated virtual devices have no direct relation to the host vector numbers of interrupts from physical devices on which they are emulated. A guest-vector assigned for a virtual device by the guest operating environment is saved by the VMM and utilized when injecting virtual interrupts on behalf of the virtual device.
- **Interrupts from assigned physical devices:** Hardware support for I/O device assignment allows physical I/O devices in the host platform to be assigned (direct-mapped) to VMs. Guest vectors for interrupts from direct-mapped physical devices take up equivalent space from the host vector space, and require the VMM to perform host-vector to guest-vector mapping for interrupts.

Figure 29-1 illustrates the functional relationship between host external interrupts and guest virtual external interrupts. Device A is owned by the host and generates external interrupts with host vector X. The host IDT is set up such that the interrupt service routine (ISR) for device driver A is hooked to host vector X as normal. VMM emulates (over device A) virtual device C in software which generates virtual interrupts to the VM with guest expected vector P. Device B is assigned to a VM and generates external interrupts with host vector Y. The host IDT is programmed to hook the VMM interrupt service routine (ISR) for assigned devices for vector Y, and the VMM handler injects virtual interrupt with guest vector Q to the VM. The guest operating system programs the guest to hook appropriate guest driver's ISR to vectors P and Q.

Figure 29-1. Host External Interrupts and Guest Virtual Interrupts

### 29.3.2 Control of Platform Interrupts

To meet the interrupt virtualization requirements, the VMM needs to take ownership of the physical interrupts and the various interrupt controllers in the platform. VMM control of physical interrupts may be enabled through the host-control settings of the “external-interrupt exiting” VM-execution control. To take ownership of the platform interrupt controllers, the VMM needs to expose the virtual interrupt controller devices to the virtual machines and restrict guest access to the platform interrupt controllers.

Intel 64 and IA-32 platforms can support three types of external interrupt control mechanisms: Programmable Interrupt Controllers (PIC), Advanced Programmable

## HANDLING BOUNDARY CONDITIONS IN A VIRTUAL MACHINE MONITOR

Interrupt Controllers (APIC), and Message Signaled Interrupts (MSI). The following sections provide information on the virtualization of each of these mechanisms.

### 29.3.2.1 PIC Virtualization

Typical PIC-enabled platform implementations support dual 8259 interrupt controllers cascaded as master and slave controllers. They supporting up to 15 possible interrupt inputs. The 8259 controllers are programmed through initialization command words (ICWx) and operation command words (OCWx) accessed through specific I/O ports. The various interrupt line states are captured in the PIC through interrupt requests, interrupt service routines and interrupt mask registers.

Guest access to the PIC I/O ports can be restricted by activating I/O bitmaps in the guest controlling-VMCS (activate-I/O-bitmap bit in VM-execution control field set to 1) and pointing the I/O-bitmap physical addresses to valid bitmap regions. Bits corresponding to the PIC I/O ports can be cleared to cause a VM exit on guest access to these ports.

If the VMM is not supporting direct access to any I/O ports from a guest, it can set the unconditional-I/O-exiting in the VM-execution control field instead of activating I/O bitmaps. The exit-reason field in VM-exit information allows identification of VM exits due to I/O access and can provide an exit-qualification to identify details about the guest I/O operation that caused the VM exit.

The VMM PIC virtualization needs to emulate the platform PIC functionality including interrupt priority, mask, request and service states, and specific guest programmed modes of PIC operation.

### 29.3.2.2 xAPIC Virtualization

Most modern Intel 64 and IA-32 platforms include support for an APIC. While the standard PIC is intended for use on uniprocessor systems, APIC can be used in either uniprocessor or multi-processor systems.

APIC based interrupt control consists of two physical components: the interrupt acceptance unit (Local APIC) which is integrated with the processor, and the interrupt delivery unit (I/O APIC) which is part of the I/O subsystem. APIC virtualization involves protecting the platform's local and I/O APICs and emulating them for the guest.

### 29.3.2.3 Local APIC Virtualization

The local APIC is responsible for the local interrupt sources, interrupt acceptance, dispensing interrupts to the logical processor, and generating inter-processor interrupts. Software interacts with the local APIC by reading and writing its memory-mapped registers residing within a 4-KByte uncached memory region with base address stored in the IA32\_APIC\_BASE MSR. Since the local APIC registers are memory-mapped, the VMM can utilize memory virtualization techniques (such as

page-table virtualization) to trap guest accesses to the page frame hosting the virtual local APIC registers.

Local APIC virtualization in the VMM needs to emulate the various local APIC operations and registers, such as: APIC identification/format registers, the local vector table (LVT), the interrupt command register (ICR), interrupt capture registers (TMR, IRR and ISR), task and processor priority registers (TPR, PPR), the EOI register and the APIC-timer register. Since local APICs are designed to operate with non-specific EOI, local APIC emulation also needs to emulate broadcast of EOI to the guest's virtual I/O APICs for level triggered virtual interrupts.

A local APIC allows interrupt masking at two levels: (1) mask bit in the local vector table entry for local interrupts and (2) raising processor priority through the TPR registers for masking lower priority external interrupts. The VMM needs to comprehend these virtual local APIC mask settings as programmed by the guest in addition to the guest virtual processor interruptibility state (when injecting APIC routed external virtual interrupts to a guest VM).

VMX provides several features which help the VMM to virtualize the local APIC. These features allow many of guest TPR accesses (using CR8 only) to occur without VM exits to the VMM:

- The VMCS contains a "virtual-APIC address" field. This 64-bit field is the physical address of the 4-KByte virtual APIC page (4-KByte aligned). The virtual-APIC page contains a TPR shadow, which is accessed by the MOV CR8 instruction. The TPR shadow comprises bits 7:4 in byte 80H of the virtual-APIC page.
- The TPR threshold: bits 3:0 of this 32-bit field determine the threshold below which the TPR shadow cannot fall. A VM exit will occur after an execution of MOV CR8 that reduces the TPR shadow below this value.
- The processor-based VM-execution controls field contains a "use TPR shadow" bit and a "CR8-store exiting" bit. If the "use TPR shadow" VM-execution control is 1 and the "CR8-store exiting" VM-execution control is 0, then a MOV from CR8 reads from the TPR shadow. If the "CR8-store exiting" VM-execution control is 1, then MOV from CR8 causes a VM exit; the "use TPR shadow" VM-execution control is ignored in this case.
- The processor-based VM-execution controls field contains a "CR8-load exiting" bit. If the "use TPR shadow" VM-execution control is set and the "CR8-load exiting" VM-execution control is clear, then MOV to CR8 writes to the "TPR shadow". A VM exit will occur after this write if the value written is below the TPR threshold. If the "CR8-load exiting" VM-execution control is set, then MOV to CR8 causes a VM exit; the "use TPR shadow" VM-execution control is ignored in this case.

### 29.3.2.4 I/O APIC Virtualization

The I/O APIC registers are typically mapped to a 1 MByte region where each I/O APIC is allocated a 4K address window within this range. The VMM may utilize physical memory virtualization to trap guest accesses to the virtual I/O APIC memory-

## HANDLING BOUNDARY CONDITIONS IN A VIRTUAL MACHINE MONITOR

mapped registers. The I/O APIC virtualization needs to emulate the various I/O APIC operations and registers such as identification/version registers, indirect-I/O-access registers, EOI register, and the I/O redirection table. I/O APIC virtualization also need to emulate various redirection table entry settings such as delivery mode, destination mode, delivery status, polarity, masking, and trigger mode programmed by the guest and track remote-IRR state on guest EOI writes to various virtual local APICs.

### 29.3.2.5 Virtualization of Message Signaled Interrupts

The *PCI Local Bus Specification* (Rev. 2.2) introduces the concept of message signaled interrupts (MSI). MSI enable PCI devices to request service by writing a system-specified message to a system specified address. The transaction address specifies the message destination while the transaction data specifies the interrupt vector, trigger mode and delivery mode. System software is expected to configure the message data and address during MSI device configuration, allocating one or more no-shared messages to MSI capable devices. Chapter 10, “Advanced Programmable Interrupt Controller (APIC),” specifies the MSI message address and data register formats to be followed on Intel 64 and IA-32 platforms. While MSI is optional for conventional PCI devices, it is the preferred interrupt mechanism for PCI-Express devices.

Since the MSI address and data are configured through PCI configuration space, to control these physical interrupts the VMM needs to assume ownership of PCI configuration space. This allows the VMM to capture the guest configuration of message address and data for MSI-capable virtual and assigned guest devices. PCI configuration transactions on PC-compatible systems are generated by software through two different methods:

1. The standard CONFIG\_ADDRESS/CONFIG\_DATA register mechanism (CFCH/CF8H ports) as defined in the *PCI Local Bus Specification*.
2. The enhanced flat memory-mapped (MEMCFG) configuration mechanism as defined in the *PCI-Express Base Specification* (Rev. 1.0a.).

The CFCH/CF8H configuration access from guests can be trapped by the VMM through use of I/O-bitmap VM-execution controls. The memory-mapped PCI-Express MEMCFG guest configuration accesses can be trapped by VMM through physical memory virtualization.

### 29.3.3 Examples of Handling of External Interrupts

The following sections illustrate interrupt processing in a VMM (when used to support the external interrupt virtualization requirements).

### 29.3.3.1 Guest Setup

The VMM sets up the guest to cause a VM exit to the VMM on external interrupts. This is done by setting the “external-interrupt exiting” VM-execution control in the guest controlling-VMCS.

### 29.3.3.2 Processor Treatment of External Interrupt

Interrupts are automatically masked by hardware in the processor on VM exit by clearing RFLAGS.IF. The exit-reason field in VMCS is set to 1 to indicate an external interrupt as the exit reason.

If the VMM is utilizing the acknowledge-on-exit feature (by setting the “acknowledge interrupt on exit” VM-exit control), the processor acknowledges the interrupt, retrieves the host vector, and saves the interrupt in the VM-exit-interruption-information field (in the VM-exit information region of the VMCS) before transitioning control to the VMM.

### 29.3.3.3 Processing of External Interrupts by VMM

Upon VM exit, the VMM can determine the exit cause of an external interrupt by checking the exit-reason field (value = 1) in VMCS. If the acknowledge-interrupt-on-exit control (see Section 21.7.1) is enabled, the VMM can use the saved host vector (in the exit-interruption-information field) to switch to the appropriate interrupt handler. If the “acknowledge interrupt on exit” VM-exit control is 0, the VMM may re-enable interrupts (by setting RFLAGS.IF) to allow vectoring of external interrupts through the monitor/host IDT.

The following steps may need to be performed by the VMM to process an external interrupt:

- **Host Owned I/O Devices:** For host-owned I/O devices, the interrupting device is owned by the VMM (or hosting OS in a hosted VMM). In this model, the interrupt service routine in the VMM/host driver is invoked and, upon ISR completion, the appropriate write sequences (TPR updates, EOI etc.) to respective interrupt controllers are performed as normal. If the work completion indicated by the driver implies virtual device activity, the VMM runs the virtual device emulation. Depending on the device class, physical device activity could imply activity by multiple virtual devices mapped over the device. For each affected virtual device, the VMM injects a virtual external interrupt event to respective guest virtual machines. The guest driver interacts with the emulated virtual device to process the virtual interrupt. The interrupt controller emulation in the VMM supports various guest accesses to the VMM’s virtual interrupt controller.
- **Guest Assigned I/O Devices:** For assigned I/O devices, either the VMM uses a software proxy or it can directly map the physical device to the assigned VM. In both cases, servicing of the interrupt condition on the physical device is initiated by the driver running inside the guest VM. With host control of external

## HANDLING BOUNDARY CONDITIONS IN A VIRTUAL MACHINE MONITOR

interrupts, interrupts from assigned physical devices cause VM exits to the VMM and vectoring through the host IDT to the registered VMM interrupt handler. To unblock delivery of other low priority platform interrupts, the VMM interrupt handler must mask the interrupt source (for level triggered interrupts) and issue the appropriate EOI write sequences.

Once the physical interrupt source is masked and the platform EOI generated, the VMM can map the host vector to its corresponding guest vector to inject the virtual interrupt into the assigned VM. The guest software does EOI write sequences to its virtual interrupt controller after completing interrupt processing. For level triggered interrupts, these EOI writes to the virtual interrupt controller may be trapped by the VMM which may in turn unmask the previously masked interrupt source.

### 29.3.3.4 Generation of Virtual Interrupt Events by VMM

The following provides some of the general steps that need to be taken by VMM designs when generating virtual interrupts:

1. Check virtual processor interruptibility state. The virtual processor interruptibility state is reflected in the guest RFLAGS.IF flag and the processor interruptibility-state saved in the guest state area of the controlling-VMCS. If RFLAGS.IF is set and the interruptibility state indicates readiness to take external interrupts (STI-masking and MOV-SS/POP-SS-masking bits are clear), the guest virtual processor is ready to take external interrupts. If the VMM design supports non-active guest sleep states, the VMM needs to make sure the current guest sleep state allows injection of external interrupt events.
2. If the guest virtual processor state is currently not interruptible, a VMM may utilize the “interrupt-window exiting” VM-execution to notify the VM (through a VM exit) when the virtual processor state changes to interruptible state.
3. Check the virtual interrupt controller state. If the guest VM exposes a virtual local APIC, the current value of its processor priority register specifies if guest software allows dispensing an external virtual interrupt with a specific priority to the virtual processor. If the virtual interrupt is routed through the local vector table (LVT) entry of the local APIC, the mask bits in the corresponding LVT entry specifies if the interrupt is currently masked. Similarly, the virtual interrupt controller’s current mask (IO-APIC or PIC) and priority settings reflect guest state to accept specific external interrupts. The VMM needs to check both the virtual processor and interrupt controller states to verify its guest interruptibility state. If the guest is currently interruptible, the VMM can inject the virtual interrupt. If the current guest state does not allow injecting a virtual interrupt, the interrupt needs to be queued by the VMM until it can be delivered.
4. Prioritize the use of VM-entry event injection. A VMM may use VM-entry event injection to deliver various virtual events (such as external interrupts, exceptions, traps, and so forth). VMM designs may prioritize use of virtual-interrupt injection between these event types. Since each VM entry allows injection of one event, depending on the VMM event priority policies, the VMM may need to queue the external virtual interrupt if a higher priority event is to be

delivered on the next VM entry. Since the VMM has masked this particular interrupt source (if it was level triggered) and done EOI to the platform interrupt controller, other platform interrupts can be serviced while this virtual interrupt event is queued for later delivery to the VM.

5. Update the virtual interrupt controller state. When the above checks have passed, before generating the virtual interrupt to the guest, the VMM updates the virtual interrupt controller state (Local-APIC, IO-APIC and/or PIC) to reflect assertion of the virtual interrupt. This involves updating the various interrupt capture registers, and priority registers as done by the respective hardware interrupt controllers. Updating the virtual interrupt controller state is required for proper interrupt event processing by guest software.
6. Inject the virtual interrupt on VM entry. To inject an external virtual interrupt to a guest VM, the VMM sets up the VM-entry interruption-information field in the guest controlling-VMCS before entry to guest using VMRESUME. Upon VM entry, the processor will use this vector to access the gate in guest's IDT and the value of RFLAGS and EIP in guest-state area of controlling-VMCS is pushed on the guest stack. If the guest RFLAGS.IF is clear, the STI-masking bit is set, or the MOV- SS/POP-SS-masking bit is set, the VM entry will fail and the processor will load state from the host-state area of the working VMCS as if a VM exit had occurred (see Section 23.7).

## 29.4 ERROR HANDLING BY VMM

Error conditions may occur during VM entries and VM exits and a few other situations. This section describes how VMM should handle these error conditions, including triple faults and machine check exceptions.

### 29.4.1 VM-Exit Failures

All VM exits load processor state from the host-state area of the VMCS that was the controlling VMCS before the VM exit. This state is checked for consistency while being loaded. Because the host-state is checked on VM entry, these checks will generally succeed. Failure is possible only if host software is incorrect or if VMCS data in the VMCS region in memory has been written by guest software (or by I/O DMA) since the last VM entry. VM exits may fail for the following reasons:

- There was a failure on storing guest MSRs.
- There was failure in loading a PDPTR.
- The controlling VMCS has been corrupted (through writes to the corresponding VMCS region) in such a way that the implementation cannot complete the VM exit.
- There was a failure on loading host MSRs.
- A machine check occurred.

## HANDLING BOUNDARY CONDITIONS IN A VIRTUAL MACHINE MONITOR

If one of these problems occurs on a VM exit, a VMX abort results.

### 29.4.2 Machine Check Considerations

The following sequence determine how machine check exceptions are handled during VMXON, VMXOFF, VM entries, and VM exits:

- VMXOFF and VMXON:

If a machine check occurs during VMXOFF or VMXON and CR4.MCE = 1, a machine-check exception (#MC) is generated. If CR4.MCE = 0, the processor goes to shutdown state.

- VM entry:

If a machine check occurs during VM entry, one of the following two treatments must occur:

- a. Normal delivery. If CR4.MCE = 1, delivery of a machine-check exception (#MC) through the host IDT occurs. If CR4.MCE = 0, the processor goes to shutdown state.
- b. Load state from the host-state area of the working VMCS as if a VM exit had occurred (see Section 23.7). The basic exit reason will be "VM-entry failure due to machine check."

If the machine check occurs after any guest state has been loaded, option b above must be used. If the machine check occurs while checking host state and VMX controls (or while reporting a failure due to such checks), option a should be preferred; however, an implementation may use b, since software will not be able to tell whether any guest state has been loaded.

- VM exit:

If a machine check occurs during VM exit, one of the following two treatments must occur:

- Normal delivery. If CR4.MCE = 1, delivery of a machine-check exception (#MC) through the guest IDT. If CR4.MCE = 0, the processor goes to shutdown state.
- Fail the VM exit. If the VM exit is to VMX root operation, a VMX abort will result; it will block events as done normally in VMX abort. The VMX abort indicator will show a machine check has induced the abort operation.

If a machine check is induced by an action in VMX non-root operation before any determination is made that the inducing action may cause a VM exit, that machine check should be considered as happening during guest execution in VMX non-root operation. This is the case even if the part of the action that caused the machine check was VMX-specific (for example: the processor's consulting an I/O bitmap). A machine-check exception will occur. If bit 12H of the exception bitmap is cleared to 0, a machine-check exception could be delivered to the guest through gate 12H of its IDT; if the bit is set to 1, the machine-check exception will cause a VM exit.

**NOTE**

The state saved in the guest-state area on VM exits due to machine-check exceptions should be considered suspect. A VMM should consult the RIPV and EIPV bits in the IA32\_MCG\_STATUS MSR before resuming a guest that caused a VM exit due to a machine-check exception.

### 29.4.3 MCA Error Handling Guidelines for VMM

Section 29.4.2 covers general requirements for VMMs to handle machine-check exceptions, when normal operation of the guest machine and/or the VMM is no longer possible. Enhancements of machine check architecture in newer processors may support software recovery of uncorrected MC errors (UCR) signaled through either machine-check exceptions or corrected machine-check interrupt (CMCI). Section 15.5 and Section 15.6 describes details of these more recent enhancements of machine check architecture.

In general, Virtual Machine Monitor (VMM) error handling should follow the recommendations for OS error handling described in Section 15.3, Section 15.6, Section 15.9, and Section 15.10. This section describes additional guidelines for hosted and native hypervisor-based VMM implementations to support corrected MC errors and recoverable uncorrected MC errors.

Because a hosted VMM provides virtualization services in the context of an existing standard host OS, the host OS controls platform hardware through the host OS services such as the standard OS device drivers. In hosted VMMs, MCA errors will be handled by the host OS error handling software.

In native VMMs, the hypervisor runs on the hardware directly, and may provide only a limited set of platform services for guest VMs. Most platform services may instead be provided by a “control OS”. In hypervisor-based VMMs, MCA errors will either be delivered directly to the VMM MCA handler (when the error is signaled while in the VMM context) or cause by a VM exit from a guest VM or be delivered to the MCA intercept handler. There are two general approaches the hypervisor can use to handle the MCA error: either within the hypervisor itself or by forwarding the error to the control OS.

#### 29.4.3.1 VMM Error Handling Strategies

Broadly speaking, there are two strategies that VMMs may take for error handling:

- Basic error handling: in this approach the guest VM is treated as any other thread of execution. If the error recovery action does not support restarting the thread after handling the error, the guest VM should be terminated.
- MCA virtualization: in this approach, the VMM virtualizes the MCA events and hardware. This enables the VMM to intercept MCA events and inject an MCA into

## HANDLING BOUNDARY CONDITIONS IN A VIRTUAL MACHINE MONITOR

the guest VM. The guest VM then has the opportunity to attempt error recovery actions, rather than being terminated by the VMM.

Details of these approaches and implementation considerations for hosted and native VMMs are discussed below.

### 29.4.3.2 Basic VMM MCA error recovery handling

The simplest approach is for the VMM to treat the guest VM as any other thread of execution:

- MCE's that occur outside the stream of execution of a virtual machine guest will cause an MCE abort and may be handled by the MCA error handler following the recovery actions and guidelines described in Section 15.9, and Section 15.10. This includes logging the error and taking appropriate recovery actions when necessary. The VMM must not resume the interrupted thread of execution or another VM until it has taken the appropriate recovery action or, in the case of fatal MCAs, reset the system.
- MCE's that occur while executing in the context of a virtual machine will be intercepted by the VMM. The MCA intercept handler may follow the error handling guidelines listed in Section 15.9 and Section 15.10 for SRAO and SRAR errors. For SRAR errors, terminating the thread of execution will involve terminating the affected guest VM. For fatal errors the MCA handler should log the error and reset the system -- the VMM should not resume execution of the interrupted VM.

### 29.4.3.3 Implementation Considerations for the Basic Model

For hosted VMMs, the host OS MCA error handling code will perform error analysis and initiate the appropriate recovery actions. For the basic model this flow does not change when terminating a guest VM although the specific actions needed to terminate a guest VM may be different than terminating an application or user process.

For native, hypervisor-based VMMs, MCA errors will either be delivered directly to the VMM MCA handler (when the error is signaled while in the VMM context) or cause a VM exit from a guest VM or be delivered to the MCA intercept handler. There are two general approaches the hypervisor can use to handle the MCA error: either by forwarding the error to the control OS or within the hypervisor itself. These approaches are described in the following paragraphs.

The hypervisor may forward the error to the control OS for handling errors. This approach simplifies the hypervisor error handling since it relies on the control OS to implement the basic error handling model. The control OS error handling code will be similar to the error handling code in the hosted VMM. Errors can be forwarded to the control OS via an OS callback or by injecting an MCE event into the control OS. Injecting an MCE will cause the control OS MCA error handler to be invoked. The control OS is responsible for terminating the affected guest VM, if necessary, which may require cooperation from the hypervisor.

Alternatively, the error may be handled completely in the hypervisor. The hypervisor error handler is enhanced to implement the basic error handling model and the hypervisor error handler has the capability to fully analyze the error information and take recovery actions based on the guidelines. In this case error handling steps in the hypervisor are similar to those for the hosted VMM described above (where the hypervisor replaces the host OS actions). The hypervisor is responsible for terminating the affected guest VM, if necessary.

In all cases, if a fatal error is detected the VMM error handler should log the error and reset the system. The VMM error handler must ensure that guest VMs are not resumed after a fatal error is detected to ensure error containment is maintained.

### 29.4.3.4 MCA Virtualization

A more sophisticated approach for handling errors is to virtualize the MCA. This involves virtualizing the MCA hardware and intercepting the MCA event in the VMM when a guest VM is interrupted by an MCA. After analyzing the error, the VMM error handler may then decide to inject an MCE abort into the guest VM for attempted guest VM error recovery. This would enable the guest OS the opportunity to take recovery actions specific to that guest.

For MCA virtualization, the VMM must provide the guest physical address for memory errors instead of the system physical address when reporting the errors to the guest VM. To compute the guest physical address, the VMM needs to maintain a reverse mapping of system physical page addresses to guest physical page addresses.

When the MCE is injected into the guest VM, the guest OS MCA handler would be invoked. The guest OS implements the MCA handling guidelines and it could potentially terminate the interrupted thread of execution within the guest instead of terminating the VM. The guest OS may also disable use of the affected page by the guest. When disabling the page the VMM error handler may handle the case where a page is shared by the VMM and a guest or by two guests. In these cases the page use must be disabled in both contexts to ensure no subsequent consumption errors are generated.

### 29.4.3.5 Implementation Considerations for the MCA Virtualization Model

MCA virtualization may be done in either hosted VMMs or hypervisor-based VMMs. The error handling flow is similar to the flow described in the basic handling case. The major difference is that the recovery action includes injecting the MCE abort into the guest VM to enable recovery by the guest OS when the MCA interrupts the execution of a guest VM.

## 29.5 HANDLING ACTIVITY STATES BY VMM

A VMM might place a logic processor in the wait-for-SIPI activity state if supporting certain guest operating system using the multi-processor (MP) start-up algorithm. A

## HANDLING BOUNDARY CONDITIONS IN A VIRTUAL MACHINE MONITOR

guest with direct access to the physical local APIC and using the MP start-up algorithm sends an INIT-SIPI-SIPI IPI sequence to start the application processor. In order to trap the SIPIs, the VMM must start the logic processor which is the target of the SIPIs in wait-for-SIPI mode.

# CHAPTER 30

## PERFORMANCE MONITORING

---

Intel 64 and IA-32 architectures provide facilities for monitoring performance.

### 30.1 PERFORMANCE MONITORING OVERVIEW

Performance monitoring was introduced in the Pentium processor with a set of model-specific performance-monitoring counter MSRs. These counters permit selection of processor performance parameters to be monitored and measured. The information obtained from these counters can be used for tuning system and compiler performance.

In Intel P6 family of processors, the performance monitoring mechanism was enhanced to permit a wider selection of events to be monitored and to allow greater control events to be monitored. Next, Pentium 4 and Intel Xeon processors introduced a new performance monitoring mechanism and new set of performance events.

The performance monitoring mechanisms and performance events defined for the Pentium, P6 family, Pentium 4, and Intel Xeon processors are not architectural. They are all model specific (not compatible among processor families). Intel Core Solo and Intel Core Duo processors support a set of architectural performance events and a set of non-architectural performance events. Processors based on Intel Core microarchitecture and Intel® Atom™ microarchitecture support enhanced architectural performance events and non-architectural performance events.

Starting with Intel Core Solo and Intel Core Duo processors, there are two classes of performance monitoring capabilities. The first class supports events for monitoring performance using counting or sampling usage. These events are non-architectural and vary from one processor model to another. They are similar to those available in Pentium M processors. These non-architectural performance monitoring events are specific to the microarchitecture and may change with enhancements. They are discussed in Section 30.3, “Performance Monitoring (Intel® Core™ Solo and Intel® Core™ Duo Processors).” Non-architectural events for a given microarchitecture can not be enumerated using CPUID; and they are listed in Appendix A, “Performance-Monitoring Events.”

The second class of performance monitoring capabilities is referred to as architectural performance monitoring. This class supports the same counting and sampling usages, with a smaller set of available events. The visible behavior of architectural performance events is consistent across processor implementations. Availability of architectural performance monitoring capabilities is enumerated using the CPUID.OAH. These events are discussed in Section 30.2.

## 30.2 ARCHITECTURAL PERFORMANCE MONITORING

Performance monitoring events are architectural when they behave consistently across microarchitectures. Intel Core Solo and Intel Core Duo processors introduced architectural performance monitoring. The feature provides a mechanism for software to enumerate performance events and provides configuration and counting facilities for events.

Architectural performance monitoring does allow for enhancement across processor implementations. The CPUID.0AH leaf provides version ID for each enhancement. Intel Core Solo and Intel Core Duo processors support base level functionality identified by version ID of 1. Processors based on Intel Core microarchitecture support, at a minimum, the base level functionality of architectural performance monitoring. Intel Core 2 Duo processor T 7700 and newer processors based on Intel Core microarchitecture support both the base level functionality and enhanced architectural performance monitoring identified by version ID of 2.

Intel Atom processor family supports the base level functionality, enhanced architectural performance monitoring identified by version ID of 2 and version ID of 3 (including two general-purpose performance counters, IA32\_PMC0, IA32\_PMC1). Intel Core i7 processor family supports the base level functionality, enhanced architectural performance monitoring identified by version ID of 2 and version ID of 3, (including four general-purpose performance counters, IA32\_PMC0-IA32\_PMC3).

### 30.2.1 Architectural Performance Monitoring Version 1

Configuring an architectural performance monitoring event involves programming performance event select registers. There are a finite number of performance event select MSRs (IA32\_PERFEVTSELx MSRs). The result of a performance monitoring event is reported in a performance monitoring counter (IA32\_PMCx MSR). Performance monitoring counters are paired with performance monitoring select registers.

Performance monitoring select registers and counters are architectural in the following respects:

- Bit field layout of IA32\_PERFEVTSELx is consistent across microarchitectures.
- Addresses of IA32\_PERFEVTSELx MSRs remain the same across microarchitectures.
- Addresses of IA32\_PMC MSRs remain the same across microarchitectures.
- Each logical processor has its own set of IA32\_PERFEVTSELx and IA32\_PMCx MSRs. Configuration facilities and counters are not shared between logical processors sharing a processor core.

Architectural performance monitoring provides a CPUID mechanism for enumerating the following information:

- Number of performance monitoring counters available in a logical processor (each IA32\_PERFEVTSELx MSR is paired to the corresponding IA32\_PMCx MSR)
- Number of bits supported in each IA32\_PMCx
- Number of architectural performance monitoring events supported in a logical processor

Software can use CPUID to discover architectural performance monitoring availability (CPUID.OAH). The architectural performance monitoring leaf provides an identifier corresponding to the version number of architectural performance monitoring available in the processor.

The version identifier is retrieved by querying CPUID.OAH:EAX[bits 7:0] (see Chapter 3, "Instruction Set Reference, A-M," in the *Intel® 64 and IA-32 Architectures Software Developer's Manual, Volume 2A*). If the version identifier is greater than zero, architectural performance monitoring capability is supported. Software queries the CPUID.OAH for the version identifier first; it then analyzes the value returned in CPUID.OAH.EAX, CPUID.OAH.EBX to determine the facilities available.

In the initial implementation of architectural performance monitoring, software can determine how many IA32\_PERFEVTSELx/ IA32\_PMCx MSR pairs are supported per

## PERFORMANCE MONITORING

core, the bit-width of PMC, and the number of architectural performance monitoring events available.

### 30.2.1.1 Architectural Performance Monitoring Version 1 Facilities

Architectural performance monitoring facilities include a set of performance monitoring counters and performance event select registers. These MSRs have the following properties:

- IA32\_PMCx MSRs start at address 0C1H and occupy a contiguous block of MSR address space; the number of MSRs per logical processor is reported using CPUID.OAH:EAX[15:8].
- IA32\_PERFEVTSELx MSRs start at address 186H and occupy a contiguous block of MSR address space. Each performance event select register is paired with a corresponding performance counter in the 0C1H address block.
- The bit width of an IA32\_PMCx MSR is reported using the CPUID.OAH:EAX[23:16]. This is the number of valid bits for read operation. On write operations, the lower-order 32 bits of the MSR may be written with any value, and the high-order bits are sign-extended from the value of bit 31.
- Bit field layout of IA32\_PERFEVTSELx MSRs is defined architecturally.

See Figure 30-1 for the bit field layout of IA32\_PERFEVTSELx MSRs. The bit fields are:

- **Event select field (bits 0 through 7)** — Selects the event logic unit used to detect microarchitectural conditions (see Table 30-1, for a list of architectural events and their 8-bit codes). The set of values for this field is defined architecturally; each value corresponds to an event logic unit for use with an architectural performance event. The number of architectural events is queried using CPUID.OAH:EAX. A processor may support only a subset of pre-defined values.

Figure 30-1. Layout of IA32\_PERFEVTSELx MSRs

- **Unit mask (UMASK) field (bits 8 through 15)** — These bits qualify the condition that the selected event logic unit detects. Valid UMASK values for each event logic unit are specific to the unit. For each architectural performance event, its corresponding UMASK value defines a specific microarchitectural condition. A pre-defined microarchitectural condition associated with an architectural event may not be applicable to a given processor. The processor then reports only a subset of pre-defined architectural events. Pre-defined architectural events are listed in Table 30-1; support for pre-defined architectural events is enumerated using CPUID.0AH:EBX. Architectural performance events available in the initial implementation are listed in Table A-1.
- **USR (user mode) flag (bit 16)** — Specifies that the selected microarchitectural condition is counted only when the logical processor is operating at privilege levels 1, 2 or 3. This flag can be used with the OS flag.
- **OS (operating system mode) flag (bit 17)** — Specifies that the selected microarchitectural condition is counted only when the logical processor is operating at privilege level 0. This flag can be used with the USR flag.
- **E (edge detect) flag (bit 18)** — Enables (when set) edge detection of the selected microarchitectural condition. The logical processor counts the number of deasserted to asserted transitions for any condition that can be expressed by the other fields. The mechanism does not permit back-to-back assertions to be distinguished.

This mechanism allows software to measure not only the fraction of time spent in a particular state, but also the average length of time spent in such a state (for example, the time spent waiting for an interrupt to be serviced).

## PERFORMANCE MONITORING

- **PC (pin control) flag (bit 19)** — When set, the logical processor toggles the PM*i* pins and increments the counter when performance-monitoring events occur; when clear, the processor toggles the PM*i* pins when the counter overflows. The toggling of a pin is defined as assertion of the pin for a single bus clock followed by deassertion.
- **INT (APIC interrupt enable) flag (bit 20)** — When set, the logical processor generates an exception through its local APIC on counter overflow.
- **EN (Enable Counters) Flag (bit 22)** — When set, performance counting is enabled in the corresponding performance-monitoring counter; when clear, the corresponding counter is disabled. The event logic unit for a UMASK must be disabled by setting IA32\_PERFEVTSELx[bit 22] = 0, before writing to IA32\_PMCx.
- **INV (invert) flag (bit 23)** — Inverts the result of the counter-mask comparison when set, so that both greater than and less than comparisons can be made.
- **Counter mask (CMASK) field (bits 24 through 31)** — When this field is not zero, a logical processor compares this mask to the events count of the detected microarchitectural condition during a single cycle. If the event count is greater than or equal to this mask, the counter is incremented by one. Otherwise the counter is not incremented.

This mask is intended for software to characterize microarchitectural conditions that can count multiple occurrences per cycle (for example, two or more instructions retired per clock; or bus queue occupations). If the counter-mask field is 0, then the counter is incremented each cycle by the event count associated with multiple occurrences.

### 30.2.2 Additional Architectural Performance Monitoring Extensions

The enhanced features provided by architectural performance monitoring version 2 include the following:

- **Fixed-function performance counter register and associated control register** — Three of the architectural performance events are counted using three fixed-function MSRs (IA32\_FIXED\_CTR0 through IA32\_FIXED\_CTR2). Each of the fixed-function PMC can count only one architectural performance event. Configuring the fixed-function PMCs is done by writing to bit fields in the MSR (IA32\_FIXED\_CTR\_CTRL) located at address 38DH. Unlike configuring performance events for general-purpose PMCs (IA32\_PMCx) via UMASK field in (IA32\_PERFEVTSELx), configuring, programming IA32\_FIXED\_CTR\_CTRL for fixed-function PMCs do not require any UMASK.
- **Simplified event programming** — Most frequent operation in programming performance events are enabling/disabling event counting and checking the status of counter overflows. Architectural performance event version 2 provides three architectural MSRs:

- IA32\_PERF\_GLOBAL\_CTRL allows software to enable/disable event counting of all or any combination of fixed-function PMCs (IA32\_FIXED\_CTRx) or any general-purpose PMCs via a single WRMSR.
- IA32\_PERF\_GLOBAL\_STATUS allows software to query counter overflow conditions on any combination of fixed-function PMCs or general-purpose PMCs via a single RDMSR.
- IA32\_PERF\_GLOBAL\_OVF\_CTRL allows software to clear counter overflow conditions on any combination of fixed-function PMCs or general-purpose PMCs via a single WRMSR.

### 30.2.2.1 Architectural Performance Monitoring Version 2 Facilities

The facilities provided by architectural performance monitoring version 2 can be queried from CPUID leaf 0AH by examining the content of register EDX:

- Bits 0 through 4 of CPUID.OAH.EDX indicates the number of fixed-function performance counters available per core,
- Bits 5 through 12 of CPUID.OAH.EDX indicates the bit-width of fixed-function performance counters. Bits beyond the width of the fixed-function counter are reserved and must be written as zeros.

#### NOTE

Early generation of processors based on Intel Core microarchitecture may report in CPUID.OAH: EDX of support for version 2 but indicating incorrect information of version 2 facilities.

The IA32\_FIXED\_CTR\_CTRL MSR include multiple sets of 4-bit field, each 4 bit field controls the operation of a fixed-function performance counter. Figure 30-2 shows the layout of 4-bit controls for each fixed-function PMC. Two sub-fields are currently defined within each control. The definitions of the bit fields are:

Figure 30-2. Layout of IA32\_FIXED\_CTR\_CTRL MSR

## PERFORMANCE MONITORING

- **Enable field (lowest 2 bits within each 4-bit control)** — When bit 0 is set, performance counting is enabled in the corresponding fixed-function performance counter to increment while the target condition associated with the architecture performance event occurred at ring 0. When bit 1 is set, performance counting is enabled in the corresponding fixed-function performance counter to increment while the target condition associated with the architecture performance event occurred at ring greater than 0. Writing 0 to both bits stops the performance counter. Writing a value of 11B enables the counter to increment irrespective of privilege levels.
- **PMI field (the fourth bit within each 4-bit control)** — When set, the logical processor generates an exception through its local APIC on overflow condition of the respective fixed-function counter.

IA32\_PERF\_GLOBAL\_CTRL MSR provides single-bit controls to enable counting of each performance counter. Figure 30-3 shows the layout of IA32\_PERF\_GLOBAL\_CTRL. Each enable bit in IA32\_PERF\_GLOBAL\_CTRL is AND'ed with the enable bits for all privilege levels in the respective IA32\_PERFEVTSELx or IA32\_PERF\_FIXED\_CTR\_CTRL MSRs to start/stop the counting of respective counters. Counting is enabled if the AND'ed results is true; counting is disabled when the result is false.

Figure 30-3. Layout of IA32\_PERF\_GLOBAL\_CTRL MSR

The fixed-function performance counters supported by architectural performance version 2 is listed in Table 30-8, the pairing between each fixed-function performance counter to an architectural performance event is also shown.

IA32\_PERF\_GLOBAL\_STATUS MSR provides single-bit status for software to query the overflow condition of each performance counter. The MSR also provides additional status bit to indicate overflow conditions when counters are programmed for precise-event-based sampling (PEBS). IA32\_PERF\_GLOBAL\_STATUS MSR also provides a sticky bit to indicate changes to the state of performance monitoring hard-

ware. Figure 30-4 shows the layout of IA32\_PERF\_GLOBAL\_STATUS. A value of 1 in bits 0, 1, 32 through 34 indicates a counter overflow condition has occurred in the associated counter.

When a performance counter is configured for PEBS, overflow condition in the counter generates a performance-monitoring interrupt signaling a PEBS event. On a PEBS event, the processor stores data records into the buffer area (see Section 18.15.5), clears the counter overflow status., and sets the “OvfBuffer” bit in IA32\_PERF\_GLOBAL\_STATUS.

Figure 30-4. Layout of IA32\_PERF\_GLOBAL\_STATUS MSR

IA32\_PERF\_GLOBAL\_OVF\_CTL MSR allows software to clear overflow indicator(s) of any general-purpose or fixed-function counters via a single WRMSR. Software should clear overflow indications when

- Setting up new values in the event select and/or UMASK field for counting or sampling
- Reloading counter values to continue sampling
- Disabling event counting or sampling.

The layout of IA32\_PERF\_GLOBAL\_OVF\_CTL is shown in Figure 30-5.

## PERFORMANCE MONITORING

Figure 30-5. Layout of IA32\_PERF\_GLOBAL\_OVF\_CTRL MSR

### 30.2.2.2 Architectural Performance Monitoring Version 3 Facilities

The facilities provided by architectural performance monitoring version 1 and 2 are also supported by architectural performance monitoring version 3. Additionally version 3 provides enhancements to support a processor core comprising of more than one logical processor, i.e. a processor core supporting Intel Hyper-Threading Technology or simultaneous multi-threading capability. Specifically,

- CPUID leaf 0AH provides enumeration mechanisms to query:
  - The number of general-purpose performance counters (IA32\_PMCx) is reported in CPUID.0AH:EAX[15:8], the bit width of general-purpose performance counters (see also Section 30.2.1.1) is reported in CPUID.0AH:EAX[23:16].
  - The bit vector representing the set of architectural performance monitoring events supported (see Section 30.2.3)
  - The number of fixed-function performance counters, the bit width of fixed-function performance counters (see also Section 30.2.2.1).
- Each general-purpose performance counter IA32\_PMCx (starting at MSR address 0C1H) is associated with a corresponding IA32\_PERFEVTSELx MSR (starting at MSR address 186H). The Bit field layout of IA32\_PERFEVTSELx MSRs is defined architecturally in Figure 30-6.

Figure 30-6. Layout of IA32\_PERFEVTSELx MSRs Supporting Architectural Performance Monitoring Version 3

**Bit 21 (AnyThread)** of IA32\_PERFEVTSELx is supported in architectural performance monitoring version 3. When set to 1, it enables counting the associated event conditions (including matching the thread's CPL with the OS/USR setting of IA32\_PERFEVTSELx) occurring across all logical processors sharing a processor core. When bit 21 is 0, the counter only increments the associated event conditions (including matching the thread's CPL with the OS/USR setting of IA32\_PERFEVTSELx) occurring in the logical processor which programmed the IA32\_PERFEVTSELx MSR.

- Each fixed-function performance counter IA32\_FIXED\_CTRx (starting at MSR address 309H) is configured by a 4-bit control block in the IA32\_PERF\_FIXED\_CTR\_CTRL MSR. The control block also allow thread-specificity configuration using an AnyThread bit. The layout of IA32\_PERF\_FIXED\_CTR\_CTRL MSR is shown.

## PERFORMANCE MONITORING

Figure 30-7. Layout of IA32\_FIXED\_CTR\_CTRL MSR Supporting Architectural Performance Monitoring Version 3

Each control block for a fixed-function performance counter provides a **AnyThread** (bit position  $2 + 4 \times N$ ,  $N = 0, 1, \dots$ ) bit. When set to 1, it enables counting the associated event conditions (including matching the thread's CPL with the ENABLE setting of the corresponding control block of IA32\_PERF\_FIXED\_CTR\_CTRL) occurring across all logical processors sharing a processor core. When an **AnyThread** bit is 0 in IA32\_PERF\_FIXED\_CTR\_CTRL, the corresponding fixed counter only increments the associated event conditions occurring in the logical processor which programmed the IA32\_PERF\_FIXED\_CTR\_CTRL MSR.

- The IA32\_PERF\_GLOBAL\_CTRL, IA32\_PERF\_GLOBAL\_STATUS, IA32\_PERF\_GLOBAL\_OVF\_CTRL MSRs provide single-bit controls/status for each general-purpose and fixed-function performance counter. Figure 30-8 shows the layout of these MSR for  $N$  general-purpose performance counters (where  $N$  is reported by CPUID.OAH:EAX[15:8]) and three fixed-function counters.

**Note:** Intel Atom processor family supports two general-purpose performance monitoring counters (i.e.  $N = 2$  in Figure 30-8), other processor families in Intel 64 architecture may support a different value of  $N$  in Figure 30-8. The number  $N$  is reported by CPUID.OAH:EAX[15:8]. Intel Core i7 processor family supports four general-purpose performance monitoring counters (i.e.  $N = 4$  in Figure 30-8)

Figure 30-8. Layout of Global Performance Monitoring Control MSR

### 30.2.2.3 Full-Width Writes to Performance Counter Registers

The general-purpose performance counter registers IA32\_PMCx are writable via WRMSR instruction. However, the value written into IA32\_PMCx by WRMSR is the signed extended 64-bit value of the EAX[31:0] input of WRMSR.

A processor that supports full-width writes to the general-purpose performance counters enumerated by CPUID.OAH:EAX[15:8] will set

## PERFORMANCE MONITORING

IA32\_PERF\_CAPABILITIES[13] to enumerate its full-width-write capability. See Figure 30-39.

If IA32\_PERF\_CAPABILITIES.FW\_WRITE[bit 13] =1, each IA32\_PMCi is accompanied by a corresponding alias address starting at 4C1H for IA32\_A\_PMCO.

If IA32\_A\_PMCi is present, the 64-bit input value (EDX:EAX) of WRMSR to IA32\_A\_PMCi will cause IA32\_PMCi to be updated by:

IA32\_PMCi[63:32]  $\leftarrow$  SignExtend(EDX[N-32:0]);

IA32\_PMCi[31:0]  $\leftarrow$  EAX[31:0];

### 30.2.3 Pre-defined Architectural Performance Events

Table 30-1 lists architecturally defined events.

**Table 30-1. UMask and Event Select Encodings for Pre-Defined Architectural Performance Events**

| Bit Position<br>CPUID.AH.EBX | Event Name                 | UMask | Event Select |
|------------------------------|----------------------------|-------|--------------|
| 0                            | UnHalted Core Cycles       | 00H   | 3CH          |
| 1                            | Instruction Retired        | 00H   | C0H          |
| 2                            | UnHalted Reference Cycles  | 01H   | 3CH          |
| 3                            | LLC Reference              | 4FH   | 2EH          |
| 4                            | LLC Misses                 | 41H   | 2EH          |
| 5                            | Branch Instruction Retired | 00H   | C4H          |
| 6                            | Branch Misses Retired      | 00H   | C5H          |

A processor that supports architectural performance monitoring may not support all the predefined architectural performance events (Table 30-1). The non-zero bits in CPUID.0AH:EBX indicate the events that are not available.

The behavior of each architectural performance event is expected to be consistent on all processors that support that event. Minor variations between microarchitectures are noted below:

- **UnHalted Core Cycles** — Event select 3CH, Umask 00H

This event counts core clock cycles when the clock signal on a specific core is running (not halted). The counter does not advance in the following conditions:

- an ACPI C-state other than C0 for normal operation
- HLT
- STPCLK# pin asserted
- being throttled by TM1

- during the frequency switching phase of a performance state transition (see Chapter 14, “Power and Thermal Management”)

The performance counter for this event counts across performance state transitions using different core clock frequencies

- **Instructions Retired** — Event select C0H, Umask 00H

This event counts the number of instructions at retirement. For instructions that consist of multiple micro-ops, this event counts the retirement of the last micro-op of the instruction. An instruction with a REP prefix counts as one instruction (not per iteration). Faults before the retirement of the last micro-op of a multi-ops instruction are not counted.

This event does not increment under VM-exit conditions. Counters continue counting during hardware interrupts, traps, and inside interrupt handlers.

- **UnHalted Reference Cycles** — Event select 3CH, Umask 01H

This event counts reference clock cycles while the clock signal on the core is running. The reference clock operates at a fixed frequency, irrespective of core frequency changes due to performance state transitions. Processors may implement this behavior differently. See Table A-10 and Table A-12 in Appendix A, “Performance-Monitoring Events.”

- **Last Level Cache References** — Event select 2EH, Umask 4FH

This event counts requests originating from the core that reference a cache line in the last level cache. The event count includes speculation and cache line fills due to the first-level cache hardware prefetcher, but may exclude cache line fills due to other hardware-prefetchers.

Because cache hierarchy, cache sizes and other implementation-specific characteristics; value comparison to estimate performance differences is not recommended.

- **Last Level Cache Misses** — Event select 2EH, Umask 41H

This event counts each cache miss condition for references to the last level cache. The event count may include speculation and cache line fills due to the first-level cache hardware prefetcher, but may exclude cache line fills due to other hardware-prefetchers.

Because cache hierarchy, cache sizes and other implementation-specific characteristics; value comparison to estimate performance differences is not recommended.

- **Branch Instructions Retired** — Event select C4H, Umask 00H

This event counts branch instructions at retirement. It counts the retirement of the last micro-op of a branch instruction.

- **All Branch Mispredict Retired** — Event select C5H, Umask 00H

This event counts mispredicted branch instructions at retirement. It counts the retirement of the last micro-op of a branch instruction in the architectural path of execution and experienced misprediction in the branch prediction hardware.

## PERFORMANCE MONITORING

Branch prediction hardware is implementation-specific across microarchitectures; value comparison to estimate performance differences is not recommended.

### NOTE

Programming decisions or software precisions on functionality should not be based on the event values or dependent on the existence of performance monitoring events.

## 30.3 PERFORMANCE MONITORING (INTEL® CORE™ SOLO AND INTEL® CORE™ DUO PROCESSORS)

In Intel Core Solo and Intel Core Duo processors, non-architectural performance monitoring events are programmed using the same facilities (see Figure 30-1) used for architectural performance events.

Non-architectural performance events use event select values that are model-specific. Event mask (Umask) values are also specific to event logic units. Some microarchitectural conditions detectable by a Umask value may have specificity related to processor topology (see Section 8.6, “Detecting Hardware Multi-Threading Support and Topology,” in the *Intel® 64 and IA-32 Architectures Software Developer’s Manual, Volume 3A*). As a result, the unit mask field (for example, IA32\_PERFEVTSELx[bits 15:8]) may contain sub-fields that specify topology information of processor cores.

The sub-field layout within the Umask field may support two-bit encoding that qualifies the relationship between a microarchitectural condition and the originating core. This data is shown in Table 30-2. The two-bit encoding for core-specificity is only supported for a subset of Umask values (see Appendix A, “Performance Monitoring Events”) and for Intel Core Duo processors. Such events are referred to as core-specific events.

**Table 30-2. Core Specificity Encoding within a Non-Architectural Umask**

| IA32_PERFEVTSELx MSRs |             |
|-----------------------|-------------|
| Bit 15:14 Encoding    | Description |
| 11B                   | All cores   |
| 10B                   | Reserved    |
| 01B                   | This core   |
| 00B                   | Reserved    |

Some microarchitectural conditions allow detection specificity only at the boundary of physical processors. Some bus events belong to this category, providing specificity between the originating physical processor (a bus agent) versus other agents on the bus. Sub-field encoding for agent specificity is shown in Table 30-3.

**Table 30-3. Agent Specificity Encoding within a Non-Architectural Umask**

| IA32_PERFEVTSELx MSRs |                    |
|-----------------------|--------------------|
| Bit 13 Encoding       | Description        |
| 0                     | This agent         |
| 1                     | Include all agents |

Some microarchitectural conditions are detectable only from the originating core. In such cases, unit mask does not support core-specificity or agent-specificity encodings. These are referred to as core-only conditions.

Some microarchitectural conditions allow detection specificity that includes or excludes the action of hardware prefetches. A two-bit encoding may be supported to qualify hardware prefetch actions. Typically, this applies only to some L2 or bus events. The sub-field encoding for hardware prefetch qualification is shown in Table 30-4.

**Table 30-4. HW Prefetch Qualification Encoding within a Non-Architectural Umask**

| IA32_PERFEVTSELx MSRs |                           |
|-----------------------|---------------------------|
| Bit 13:12 Encoding    | Description               |
| 11B                   | All inclusive             |
| 10B                   | Reserved                  |
| 01B                   | Hardware prefetch only    |
| 00B                   | Exclude hardware prefetch |

Some performance events may (a) support none of the three event-specific qualification encodings (b) may support core-specificity and agent specificity simultaneously (c) or may support core-specificity and hardware prefetch qualification simultaneously. Agent-specificity and hardware prefetch qualification are mutually exclusive.

In addition, some L2 events permit qualifications that distinguish cache coherent states. The sub-field definition for cache coherency state qualification is shown in Table 30-5. If no bits in the MESI qualification sub-field are set for an event that requires setting MESI qualification bits, the event count will not increment.

**Table 30-5. MESI Qualification Definitions within a Non-Architectural Umask**

| IA32_PERFEVTSELx MSRs |                        |
|-----------------------|------------------------|
| Bit Position 11:8     | Description            |
| Bit 11                | Counts modified state  |
| Bit 10                | Counts exclusive state |

## PERFORMANCE MONITORING

**Table 30-5. MESI Qualification Definitions within a Non-Architectural Umask**

| IA32_PERFEVTSELx MSRs |                      |
|-----------------------|----------------------|
| Bit Position 11:8     | Description          |
| Bit 9                 | Counts shared state  |
| Bit 8                 | Counts Invalid state |

## 30.4 PERFORMANCE MONITORING (PROCESSORS BASED ON INTEL® CORE™ MICROARCHITECTURE)

In addition to architectural performance monitoring, processors based on the Intel Core microarchitecture support non-architectural performance monitoring events.

Architectural performance events can be collected using general-purpose performance counters. Non-architectural performance events can be collected using general-purpose performance counters (coupled with two IA32\_PERFEVTSELx MSRs for detailed event configurations), or fixed-function performance counters (see Section 30.4.1). IA32\_PERFEVTSELx MSRs are architectural; their layout is shown in Figure 30-1. Starting with Intel Core 2 processor T 7700, fixed-function performance counters and associated counter control and status MSR becomes part of architectural performance monitoring version 2 facilities (see also Section 30.2.2).

Non-architectural performance events in processors based on Intel Core microarchitecture use event select values that are model-specific. Valid event mask (Umask) bits are listed in Appendix A. The UMASK field may contain sub-fields identical to those listed in Table 30-2, Table 30-3, Table 30-4, and Table 30-5. One or more of these sub-fields may apply to specific events on an event-by-event basis. Details are listed in Table A-10 in Appendix A, “Performance-Monitoring Events.”

In addition, the UMASK field may also contain a sub-field that allows detection specificity related to snoop responses. Bits of the snoop response qualification sub-field are defined in Table 30-6.

**Table 30-6. Bus Snoop Qualification Definitions within a Non-Architectural Umask**

| IA32_PERFEVTSELx MSRs |                |
|-----------------------|----------------|
| Bit Position 11:8     | Description    |
| Bit 11                | HITM response  |
| Bit 10                | Reserved       |
| Bit 9                 | HIT response   |
| Bit 8                 | CLEAN response |

There are also non-architectural events that support qualification of different types of snoop operation. The corresponding bit field for snoop type qualification are listed in Table 30-7.

**Table 30-7. Snoop Type Qualification Definitions within a Non-Architectural Umask**

| IA32_PERFEVTSELx MSRs |              |
|-----------------------|--------------|
| Bit Position 9:8      | Description  |
| Bit 9                 | CMP2I snoops |
| Bit 8                 | CMP2S snoops |

No more than one sub-field of MESI, snoop response, and snoop type qualification sub-fields can be supported in a performance event.

#### NOTE

Software must write known values to the performance counters prior to enabling the counters. The content of general-purpose counters and fixed-function counters are undefined after INIT or RESET.

#### 30.4.1 Fixed-function Performance Counters

Processors based on Intel Core microarchitecture provide three fixed-function performance counters. Bits beyond the width of the fixed counter are reserved and must be written as zeros. Model-specific fixed-function performance counters on processors that support Architectural Perfmon version 1 are 40 bits wide.

Each of the fixed-function counter is dedicated to count a pre-defined performance monitoring events. The performance monitoring events associated with fixed-function counters and the addresses of these counters are listed in Table 30-8.

**Table 30-8. Association of Fixed-Function Performance Counters with Architectural Performance Events**

| Event Name            | Fixed-Function PMC                       | PMC Address |
|-----------------------|------------------------------------------|-------------|
| INST_RETIREANY        | MSR_PERF_FIXED_CTR0/I<br>IA32_FIXED_CTR0 | 309H        |
| CPU_CLK_UNHALTED.CORE | MSR_PERF_FIXED_CTR1//<br>IA32_FIXED_CTR1 | 30AH        |
| CPU_CLK_UNHALTED.REF  | MSR_PERF_FIXED_CTR2//<br>IA32_FIXED_CTR2 | 30BH        |

Programming the fixed-function performance counters does not involve any of the

## PERFORMANCE MONITORING

IA32\_PERFEVTSELx MSRs, and does not require specifying any event masks. Instead, the MSR MSR\_PERF\_FIXED\_CTR\_CTRL provides multiple sets of 4-bit fields; each 4-bit field controls the operation of a fixed-function performance counter (PMC). See Figures 30-9. Two sub-fields are defined for each control. See Figure 30-9; bit fields are:

- **Enable field (low 2 bits in each 4-bit control)** — When bit 0 is set, performance counting is enabled in the corresponding fixed-function performance counter to increment when the target condition associated with the architecture performance event occurs at ring 0.

When bit 1 is set, performance counting is enabled in the corresponding fixed-function performance counter to increment when the target condition associated with the architecture performance event occurs at ring greater than 0.

Writing 0 to both bits stops the performance counter. Writing 11B causes the counter to increment irrespective of privilege levels.

Figure 30-9. Layout of MSR\_PERF\_FIXED\_CTR\_CTRL MSR

- **PMI field (fourth bit in each 4-bit control)** — When set, the logical processor generates an exception through its local APIC on overflow condition of the respective fixed-function counter.

### 30.4.2 Global Counter Control Facilities

Processors based on Intel Core microarchitecture provides simplified performance counter control that simplifies the most frequent operations in programming performance events, i.e. enabling/disabling event counting and checking the status of counter overflows. This is done by the following three MSRs:

- MSR\_PERF\_GLOBAL\_CTRL enables/disables event counting for all or any combination of fixed-function PMCs (MSR\_PERF\_FIXED\_CTRx) or general-purpose PMCs via a single WRMSR.

- MSR\_PERF\_GLOBAL\_STATUS allows software to query counter overflow conditions on any combination of fixed-function PMCs (MSR\_PERF\_FIXED\_CTRx) or general-purpose PMCs via a single RDMSR.
- MSR\_PERF\_GLOBAL\_OVF\_CTRL allows software to clear counter overflow conditions on any combination of fixed-function PMCs (MSR\_PERF\_FIXED\_CTRx) or general-purpose PMCs via a single WRMSR.

MSR\_PERF\_GLOBAL\_CTRL MSR provides single-bit controls to enable counting in each performance counter (see Figure 30-10). Each enable bit in MSR\_PERF\_GLOBAL\_CTRL is AND'ed with the enable bits for all privilege levels in the respective IA32\_PERFEVTSELx or MSR\_PERF\_FIXED\_CTR\_CTRL MSRs to start/stop the counting of respective counters. Counting is enabled if the AND'ed results is true; counting is disabled when the result is false.

Figure 30-10. Layout of MSR\_PERF\_GLOBAL\_CTRL MSR

MSR\_PERF\_GLOBAL\_STATUS MSR provides single-bit status used by software to query the overflow condition of each performance counter. The MSR also provides additional status bit to indicate overflow conditions when counters are programmed for precise-event-based sampling (PEBS). The MSR\_PERF\_GLOBAL\_STATUS MSR also provides a 'sticky bit' to indicate changes to the state of performance monitoring hardware (see Figure 30-11). A value of 1 in bits 34:32, 1, 0 indicates an overflow condition has occurred in the associated counter.

## PERFORMANCE MONITORING

Figure 30-11. Layout of MSR\_PERF\_GLOBAL\_STATUS MSR

When a performance counter is configured for PEBS, an overflow condition in the counter generates a performance-monitoring interrupt this signals a PEBS event. On a PEBS event, the processor stores data records in the buffer area (see Section 16.4.9), clears the counter overflow status, and sets the OvfBuffer bit in MSR\_PERF\_GLOBAL\_STATUS.

MSR\_PERF\_GLOBAL\_OVF\_CTRL MSR allows software to clear overflow the indicators for general-purpose or fixed-function counters via a single WRMSR (see Figure 30-12). Clear overflow indications when:

- Setting up new values in the event select and/or UMASK field for counting or sampling
- Reloading counter values to continue sampling
- Disabling event counting or sampling

Figure 30-12. Layout of MSR\_PERF\_GLOBAL\_OVF\_CTRL MSR

### 30.4.3 At-Retirement Events

Many non-architectural performance events are impacted by the speculative nature of out-of-order execution. A subset of non-architectural performance events on processors based on Intel Core microarchitecture are enhanced with a tagging mechanism (similar to that found in Intel NetBurst® microarchitecture) that exclude contributions that arise from speculative execution. The at-retirement events available in processors based on Intel Core microarchitecture does not require special MSR programming control (see Section 30.9.6, "At-Retirement Counting"), but is limited to IA32\_PMCO. See Table 30-9 for a list of events available to processors based on Intel Core microarchitecture.

**Table 30-9. At-Retirement Performance Events for Intel Core Microarchitecture**

| Event Name                    | UMask | Event Select |
|-------------------------------|-------|--------------|
| ITLB_MISS_RETIRE              | 00H   | C9H          |
| MEM_LOAD_RETIRE.L1D_MISS      | 01H   | CBH          |
| MEM_LOAD_RETIRE.L1D_LINE_MISS | 02H   | CBH          |
| MEM_LOAD_RETIRE.L2_MISS       | 04H   | CBH          |
| MEM_LOAD_RETIRE.L2_LINE_MISS  | 08H   | CBH          |
| MEM_LOAD_RETIRE.DTLB_MISS     | 10H   | CBH          |

### 30.4.4 Precise Event Based Sampling (PEBS)

Processors based on Intel Core microarchitecture also support precise event based sampling (PEBS). This feature was introduced by processors based on Intel NetBurst microarchitecture.

PEBS uses a debug store mechanism and a performance monitoring interrupt to store a set of architectural state information for the processor. The information provides architectural state of the instruction executed after the instruction that caused the event (See Section 30.4.4.2).

In cases where the same instruction causes BTS and PEBS to be activated, PEBS is processed before BTS are processed. The PMI request is held until the processor completes processing of PEBS and BTS.

For processors based on Intel Core microarchitecture, events that support precise sampling are listed in Table 30-10. The procedure for detecting availability of PEBS is the same as described in Section 30.9.7.1.

**Table 30-10. PEBS Performance Events for Intel Core Microarchitecture**

| Event Name         | UMask | Event Select |
|--------------------|-------|--------------|
| INSTR_RETIRE.ANY_P | 00H   | C0H          |
| X87_OPS_RETIRE.ANY | FEH   | C1H          |

**Table 30-10. PEBS Performance Events for Intel Core Microarchitecture (Contd.)**

| Event Name                     | UMask | Event Select |
|--------------------------------|-------|--------------|
| BR_INST_RETIRED.MISPRED        | 00H   | C5H          |
| SIMD_INST_RETIRED.ANY          | 1FH   | C7H          |
| MEM_LOAD_RETIRED.L1D_MISS      | 01H   | CBH          |
| MEM_LOAD_RETIRED.L1D_LINE_MISS | 02H   | CBH          |
| MEM_LOAD_RETIRED.L2_MISS       | 04H   | CBH          |
| MEM_LOAD_RETIRED.L2_LINE_MISS  | 08H   | CBH          |
| MEM_LOAD_RETIRED.DTLB_MISS     | 10H   | CBH          |

#### 30.4.4.1 Setting up the PEBS Buffer

For processors based on Intel Core microarchitecture, PEBS is available using IA32\_PMC0 only. Use the following procedure to set up the processor and IA32\_PMC0 counter for PEBS:

1. Set up the precise event buffering facilities. Place values in the precise event buffer base, precise event index, precise event absolute maximum, precise event interrupt threshold, and precise event counter reset fields of the DS buffer management area. In processors based on Intel Core microarchitecture, PEBS records consist of 64-bit address entries. See Figure 16-8 to set up the precise event records buffer in memory.
2. Enable PEBS. Set the Enable PEBS on PMCO flag (bit 0) in IA32\_PEBS\_ENABLE MSR.
3. Set up the IA32\_PMC0 performance counter and IA32\_PERFEVTSEL0 for an event listed in Table 30-10.

#### 30.4.4.2 PEBS Record Format

The PEBS record format may be extended across different processor implementations. The IA32\_PERF\_CAPABILITIES MSR defines a mechanism for software to handle the evolution of PEBS record format in processors that support architectural performance monitoring with version id equals 2 or higher. The bit fields of IA32\_PERF\_CAPABILITIES are defined in Table B-2 of Appendix B, “Model-Specific Registers (MSRs)”. The relevant bit fields that governs PEBS are:

- PEBSTrap [bit 6]: When set, PEBS recording is trap-like. After the PEBS-enabled counter has overflowed, PEBS record is recorded for the next PEBS-able event at the completion of the sampled instruction causing the PEBS event. When clear, PEBS recording is fault-like. The PEBS record is recorded before the sampled instruction causing the PEBS event.
- PEBSSaveArchRegs [bit 7]: When set, PEBS will save architectural register and state information according to the encoded value of the PEBSRecordFormat field. On processors based on Intel Core microarchitecture, this bit is always 1

- PEBSRecordFormat [bits 11:8]: Valid encodings are:
  - 0000B: Only general-purpose registers, instruction pointer and RFLAGS registers are saved in each PEBS record (seeSection 30.9.7).

### 30.4.4.3 Writing a PEBS Interrupt Service Routine

The PEBS facilities share the same interrupt vector and interrupt service routine (called the DS ISR) with the non-precise event-based sampling and BTS facilities. To handle PEBS interrupts, PEBS handler code must be included in the DS ISR. See Section 16.4.9.1, “DS Save Area and IA-32e Mode Operation,” for guidelines when writing the DS ISR.

The service routine can query MSR\_PERF\_GLOBAL\_STATUS to determine which counter(s) caused of overflow condition. The service routine should clear overflow indicator by writing to MSR\_PERF\_GLOBAL\_OVF\_CTL.

A comparison of the sequence of requirements to program PEBS for processors based on Intel Core and Intel NetBurst microarchitectures is listed in Table 30-11.

Table 30-11. Requirements to Program PEBS

|                                     | For Processors based on Intel Core microarchitecture                                                                                                                                                                                                                                                                                                                                     | For Processors based on Intel NetBurst microarchitecture |
|-------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------|
| Verify PEBS support of processor/OS | <ul style="list-style-type: none"> <li>▪ IA32_MISC_ENABLE.EMON_AVAILABE (bit 7) is set.</li> <li>▪ IA32_MISC_ENABLE.PEBS_UNAVAILABE (bit 12) is clear.</li> </ul>                                                                                                                                                                                                                        |                                                          |
| Ensure counters are in disabled     | On initial set up or changing event configurations, write MSR_PERF_GLOBAL_CTRL MSR (0x38F) with 0.<br>On subsequent entries: <ul style="list-style-type: none"> <li>▪ Clear all counters if “Counter Freeze on PMI” is not enabled.</li> <li>▪ If IA32_DebugCTL.Freeze is enabled, counters are automatically disabled.</li> </ul> Counters MUST be stopped before writing. <sup>1</sup> | Optional                                                 |
| Disable PEBS.                       | Clear ENABLE PMCO bit in IA32_PEBS_ENABLE MSR (0x3F1).                                                                                                                                                                                                                                                                                                                                   | Optional                                                 |
| Check overflow conditions.          | Check MSR_PERF_GLOBAL_STATUS MSR (0x38E) handle any overflow conditions.                                                                                                                                                                                                                                                                                                                 | Check OVF flag of each CCCR for overflow condition       |

## PERFORMANCE MONITORING

Table 30-11. Requirements to Program PEBS (Contd.)

|                                               | For Processors based on Intel Core microarchitecture                                                                                                                                            | For Processors based on Intel NetBurst microarchitecture                                                                                     |

| Allocate buffer for PEBS states.              | Allocate a buffer in memory for the precise information.                                                                                                                                        |                                                                                                                                              |
| Program the IA32_DS_AREA MSR.                 | Program the IA32_DS_AREA MSR.                                                                                                                                                                   |                                                                                                                                              |
| Configure the PEBS buffer management records. | Configure the PEBS buffer management records in the DS buffer management area.                                                                                                                  |                                                                                                                                              |
| Configure/Enable PEBS.                        | Set Enable PMCO bit in IA32_PEBS_ENABLE MSR (0x3F1).                                                                                                                                            | Configure MSR_PEBS_ENABLE, MSR_PEBS_MATRIX_VERT and MSR_PEBS_MATRIX_HORZ as needed.                                                          |
| Enable counters.                              | Set Enable bits in MSR_PERF_GLOBAL_CTRL MSR (0x38F).                                                                                                                                            | Set each CCCR enable bit 12 - 1.                                                                                                             |

NOTES:

1. Counters read while enabled are not guaranteed to be precise with event counts that occur in timing proximity to the RDMSR.

### 30.4.4.4 Re-configuring PEBS Facilities

When software needs to reconfigure PEBS facilities, it should allow a quiescent period between stopping the prior event counting and setting up a new PEBS event. The quiescent period is to allow any latent residual PEBS records to complete its capture at their previously specified buffer address (provided by IA32\_DS\_AREA).

## 30.5 PERFORMANCE MONITORING (PROCESSORS BASED ON INTEL® ATOM™ MICROARCHITECTURE)

Intel Atom processor family supports architectural performance monitoring capability with version ID 3 (see Section 30.2.2.2) and a host of non-architectural monitoring capabilities. The initial implementation of Intel Atom processor family provides two general-purpose performance counters (IA32\_PMC0, IA32\_PMC1) and three fixed-function performance counters (IA32\_FIXED\_CTR0, IA32\_FIXED\_CTR1, IA32\_FIXED\_CTR2).

Non-architectural performance monitoring in Intel Atom processor family uses the IA32\_PERFEVTSELx MSR to configure a set of non-architecture performance monitoring events to be counted by the corresponding general-purpose performance counter. The list of non-architectural performance monitoring events is listed in Table A-11.

Architectural and non-architectural performance monitoring events in Intel Atom processor family support thread qualification using bit 21 of IA32\_PERFEVTSELx MSR.

The bit fields within each IA32\_PERFEVTSELx MSR are defined in Figure 30-6 and described in Section 30.2.1.1 and Section 30.2.2.2.

Valid event mask (Umask) bits are listed in Appendix A. The UMASK field may contain sub-fields that provide the same qualifying actions like those listed in Table 30-2, Table 30-3, Table 30-4, and Table 30-5. One or more of these sub-fields may apply to specific events on an event-by-event basis. Details are listed in Table A-11 in Appendix A, “Performance-Monitoring Events.” Precise Event Based Monitoring is supported using IA32\_PMC0 (see also Section 16.4.9, “BTS and DS Save Area”).

## 30.6 PERFORMANCE MONITORING FOR PROCESSORS BASED ON INTEL® MICROARCHITECTURE CODE NAME NEHALEM

Intel Core i7 processor family<sup>1</sup> supports architectural performance monitoring capability with version ID 3 (see Section 30.2.2.2) and a host of non-architectural monitoring capabilities. The Intel Core i7 processor family is based on Intel® microarchitecture code name Nehalem, and provides four general-purpose performance counters (IA32\_PMC0, IA32\_PMC1, IA32\_PMC2, IA32\_PMC3) and three fixed-function performance counters (IA32\_FIXED\_CTR0, IA32\_FIXED\_CTR1, IA32\_FIXED\_CTR2) in the processor core.

---

1. Intel Xeon processor 5500 series and 3400 series are also based on Intel microarchitecture code name Nehalem, so the performance monitoring facilities described in this section generally also apply.

## PERFORMANCE MONITORING

Non-architectural performance monitoring in Intel Core i7 processor family uses the IA32\_PERFEVTSELx MSR to configure a set of non-architecture performance monitoring events to be counted by the corresponding general-purpose performance counter. The list of non-architectural performance monitoring events is listed in Table A-11. Non-architectural performance monitoring events fall into two broad categories:

- Performance monitoring events in the processor core: These include many events that are similar to performance monitoring events available to processor based on Intel Core microarchitecture. Additionally, there are several enhancements in the performance monitoring capability for detecting microarchitectural conditions in the processor core or in the interaction of the processor core to the off-core sub-systems in the physical processor package. The off-core sub-systems in the physical processor package is loosely referred to as "uncore".
- Performance monitoring events in the uncore: The uncore sub-system is shared by more than one processor cores in the physical processor package. It provides additional performance monitoring facility outside of IA32\_PMCx and performance monitoring events that are specific to the uncore sub-system.

Architectural and non-architectural performance monitoring events in Intel Core i7 processor family support thread qualification using bit 21 of IA32\_PERFEVTSELx MSR.

The bit fields within each IA32\_PERFEVTSELx MSR are defined in Figure 30-6 and described in Section 30.2.1.1 and Section 30.2.2.2.

Figure 30-13. IA32\_PERF\_GLOBAL\_STATUS MSR

### 30.6.1 Enhancements of Performance Monitoring in the Processor Core

The notable enhancements in the monitoring of performance events in the processor core include:

- Four general purpose performance counters, IA32\_PMCx, associated counter configuration MSRs, IA32\_PERFEVTSELx, and global counter control MSR supporting simplified control of four counters. Each of the four performance counter can support precise event based sampling (PEBS) and thread-qualification of architectural and non-architectural performance events. Width of IA32\_PMCx supported by hardware has been increased. The width of counter reported by CPUID.0AH:EAX[23:16] is 48 bits. The PEBS facility in Intel microarchitecture code name Nehalem has been enhanced to include new data format to capture additional information, such as load latency.
- Load latency sampling facility. Average latency of memory load operation can be sampled using load-latency facility in processors based on Intel microarchitecture code name Nehalem. The facility can measure average latency of load micro-operations from dispatch to when data is globally observable (GO). This facility is used in conjunction with the PEBS facility.
- Off-core response counting facility. This facility in the processor core allows software to count certain transaction responses between the processor core to sub-systems outside the processor core (uncore). Counting off-core response requires additional event qualification configuration facility in conjunction with IA32\_PERFEVTSELx. Two off-core response MSRs are provided to use in conjunction with specific event codes that must be specified with IA32\_PERFEVTSELx.

#### 30.6.1.1 Precise Event Based Sampling (PEBS)

All four general-purpose performance counters, IA32\_PMCx, can be used for PEBS if the performance event supports PEBS. Software uses IA32\_MISC\_ENABLE[7] and IA32\_MISC\_ENABLE[12] to detect whether the performance monitoring facility and PEBS functionality are supported in the processor. The MSR IA32\_PEBS\_ENABLE provides 4 bits that software must use to enable which IA32\_PMCx overflow condition will cause the PEBS record to be captured.

Additionally, the PEBS record is expanded to allow latency information to be captured. The MSR IA32\_PEBS\_ENABLE provides 4 additional bits that software must use to enable latency data recording in the PEBS record upon the respective IA32\_PMCx overflow condition. The layout of IA32\_PEBS\_ENABLE for processors based on Intel microarchitecture code name Nehalem is shown in Figure 30-14.

When a counter is enabled to capture machine state (PEBS\_EN\_PMCx = 1), the processor will write machine state information to a memory buffer specified by software as detailed below. When the counter IA32\_PMCx overflows from maximum count to zero, the PEBS hardware is armed.

## PERFORMANCE MONITORING

Figure 30-14. Layout of IA32\_PEBS\_ENABLE MSR

Upon occurrence of the next PEBS event, the PEBS hardware triggers an assist and causes a PEBS record to be written. The format of the PEBS record is indicated by the bit field IA32\_PERF\_CAPABILITIES[11:8] (see Figure 30-39).

The behavior of PEBS assists is reported by IA32\_PERF\_CAPABILITIES[6] (see Figure 30-39). The return instruction pointer (RIP) reported in the PEBS record will point to the instruction after (+1) the instruction that causes the PEBS assist. The machine state reported in the PEBS record is the machine state after the instruction that causes the PEBS assist is retired. For instance, if the instructions:

```
mov eax, [eax] ; causes PEBS assist
nop
```

are executed, the PEBS record will report the address of the nop, and the value of EAX in the PEBS record will show the value read from memory, not the target address of the read operation.

The PEBS record format is shown in Table 30-12, and each field in the PEBS record is 64 bits long. The PEBS record format, along with debug/store area storage format, does not change regardless of IA-32e mode is active or not.

CPUID.01H:ECX.DTES64[bit 2] reports the processor's support for 64-bit debug/store area storage format is invariant to IA-32e mode.

Table 30-12. PEBS Record Format for Intel Core i7 Processor Family

| Byte Offset | Field    | Byte Offset | Field |
|-------------|----------|-------------|-------|
| 0x0         | R/EFLAGS | 0x58        | R9    |

Table 30-12. PEBS Record Format for Intel Core i7 Processor Family

| Byte Offset | Field | Byte Offset | Field                       |
|-------------|-------|-------------|-----------------------------|
| 0x8         | R/EIP | 0x60        | R10                         |
| 0x10        | R/EAX | 0x68        | R11                         |
| 0x18        | R/EBX | 0x70        | R12                         |
| 0x20        | R/ECX | 0x78        | R13                         |
| 0x28        | R/EDX | 0x80        | R14                         |
| 0x30        | R/ESI | 0x88        | R15                         |
| 0x38        | R/EDI | 0x90        | IA32_PERF_GLOBAL_STATUS     |
| 0x40        | R/EBP | 0x98        | Data Linear Address         |
| 0x48        | R/ESP | 0xA0        | Data Source Encoding        |
| 0x50        | R8    | 0xA8        | Latency value (core cycles) |

In IA-32e mode, the full 64-bit value is written to the register. If the processor is not operating in IA-32e mode, 32-bit value is written to registers with bits 63:32 zeroed. Registers not defined when the processor is not in IA-32e mode are written to zero.

Bytes 0xAF:0x90 are enhancement to the PEBS record format. Support for this enhanced PEBS record format is indicated by IA32\_PERF\_CAPABILITIES[11:8] encoding of 0001B.

The value written to bytes 0x97:0x90 is the state of the IA32\_PERF\_GLOBAL\_STATUS register before the PEBS assist occurred. This value is written so software can determine which counters overflowed when this PEBS record was written. Note that this field indicates the overflow status for all counters, regardless of whether they were programmed for PEBS or not.

### Programming PEBS Facility

Only a subset of non-architectural performance events in the processor support PEBS. The subset of precise events are listed in Table 30-10. In addition to using IA32\_PERFEVTSELx to specify event unit/mask settings and setting the EN\_PMCx bit in the IA32\_PEBS\_ENABLE register for the respective counter, the software must also initialize the DS\_BUFFER\_MANAGEMENT\_AREA data structure in memory to support capturing PEBS records for precise events.

### NOTE

PEBS events are only valid when the following fields of IA32\_PERFEVTSELx are all zero: AnyThread, Edge, Invert, CMask.

The beginning linear address of the DS\_BUFFER\_MANAGEMENT\_AREA data structure must be programmed into the IA32\_DS\_AREA register. The layout of the DS\_BUFFER\_MANAGEMENT\_AREA is shown in Figure 30-15.

## PERFORMANCE MONITORING

- **PEBS Buffer Base:** This field is programmed with the linear address of the first byte of the PEBS buffer allocated by software. The processor reads this field to determine the base address of the PEBS buffer. Software should allocate this memory from the non-paged pool.

Figure 30-15. PEBS Programming Environment

- **PEBS Index:** This field is initially programmed with the same value as the PEBS Buffer Base field, or the beginning linear address of the PEBS buffer. The processor reads this field to determine the location of the next PEBS record to write to. After a PEBS record has been written, the processor also updates this field with the address of the next PEBS record to be written. The figure above illustrates the state of PEBS Index after the first PEBS record is written.

- **PEBS Absolute Maximum:** This field represents the absolute address of the maximum length of the allocated PEBS buffer plus the starting address of the PEBS buffer. The processor will not write any PEBS record beyond the end of PEBS buffer, when **PEBS Index** equals **PEBS Absolute Maximum**. No signaling is generated when PEBS buffer is full. Software must reset the **PEBS Index** field to the beginning of the PEBS buffer address to continue capturing PEBS records.
- **PEBS Interrupt Threshold:** This field specifies the threshold value to trigger a performance interrupt and notify software that the PEBS buffer is nearly full. This field is programmed with the linear address of the first byte of the PEBS record within the PEBS buffer that represents the threshold record. After the processor writes a PEBS record and updates **PEBS Index**, if the **PEBS Index** reaches the threshold value of this field, the processor will generate a performance interrupt. This is the same interrupt that is generated by a performance counter overflow, as programmed in the Performance Monitoring Counters vector in the Local Vector Table of the Local APIC. When a performance interrupt due to PEBS buffer full is generated, the IA32\_PERF\_GLOBAL\_STATUS.PEBS\_Ovf bit will be set.
- **PEBS CounterX Reset:** This field allows software to set up PEBS counter overflow condition to occur at a rate useful for profiling workload, thereby generating multiple PEBS records to facilitate characterizing the profile the execution of test code. After each PEBS record is written, the processor checks each counter to see if it overflowed and was enabled for PEBS (the corresponding bit in IA32\_PEBS\_ENABLED was set). If these conditions are met, then the reset value for each overflowed counter is loaded from the DS Buffer Management Area. For example, if counter IA32\_PMC0 caused a PEBS record to be written, then the value of “PEBS Counter 0 Reset” would be written to counter IA32\_PMC0. If a counter is not enabled for PEBS, its value will not be modified by the PEBS assist.

#### Performance Counter Prioritization

Performance monitoring interrupts are triggered by a counter transitioning from maximum count to zero (assuming IA32\_PerfEvtSelX.INT is set). This same transition will cause PEBS hardware to arm, but not trigger. PEBS hardware triggers upon detection of the first PEBS event after the PEBS hardware has been armed (a 0 to 1 transition of the counter). At this point, a PEBS assist will be undertaken by the processor.

Performance counters (fixed and general-purpose) are prioritized in index order. That is, counter IA32\_PMC0 takes precedence over all other counters. Counter IA32\_PMC1 takes precedence over counters IA32\_PMC2 and IA32\_PMC3, and so on. This means that if simultaneous overflows or PEBS assists occur, the appropriate action will be taken for the highest priority performance counter. For example, if IA32\_PMC1 cause an overflow interrupt and IA32\_PMC2 causes an PEBS assist simultaneously, then the overflow interrupt will be serviced first.

The PEBS threshold interrupt is triggered by the PEBS assist, and is by definition prioritized lower than the PEBS assist. Hardware will not generate separate interrupts for each counter that simultaneously overflows. General-purpose performance counters are prioritized over fixed counters.

## PERFORMANCE MONITORING

If a counter is programmed with a precise (PEBS-enabled) event and programmed to generate a counter overflow interrupt, the PEBS assist is serviced before the counter overflow interrupt is serviced. If in addition the PEBS interrupt threshold is met, the threshold interrupt is generated after the PEBS assist completes, followed by the counter overflow interrupt (two separate interrupts are generated).

Uncore counters may be programmed to interrupt one or more processor cores (see Section 30.6.2). It is possible for interrupts posted from the uncore facility to occur coincident with counter overflow interrupts from the processor core. Software must check core and uncore status registers to determine the exact origin of counter overflow interrupts.

### 30.6.1.2 Load Latency Performance Monitoring Facility

The load latency facility provides software a means to characterize the average load latency to different levels of cache/memory hierarchy. This facility requires processor supporting enhanced PEBS record format in the PEBS buffer, see Table 30-12. The facility measures latency from micro-operation (uop) dispatch to when data is globally observable (GO).

To use this feature software must assure:

- One of the IA32\_PERFEVTSELx MSR is programmed to specify the event unit MEM\_INST\_RETIRED, and the LATENCY\_ABOVE\_THRESHOLD event mask must be specified (IA32\_PerfEvtSelX[15:0] = 0x100H). The corresponding counter IA32\_PMCx will accumulate event counts for architecturally visible loads which exceed the programmed latency threshold specified separately in a MSR. Stores are ignored when this event is programmed. The CMASK or INV fields of the IA32\_PerfEvtSelX register used for counting load latency must be 0. Writing other values will result in undefined behavior.
- The MSR\_PEBS\_LD\_LAT\_THRESHOLD MSR is programmed with the desired latency threshold in core clock cycles. Loads with latencies greater than this value are eligible for counting and latency data reporting. The minimum value that may be programmed in this register is 3 (the minimum detectable load latency is 4 core clock cycles).
- The PEBS enable bit in the IA32\_PEBS\_ENABLE register is set for the corresponding IA32\_PMCx counter register. This means that both the PEBS\_EN\_CTRX and LL\_EN\_CTRX bits must be set for the counter(s) of interest. For example, to enable load latency on counter IA32\_PMC0, the IA32\_PEBS\_ENABLE register must be programmed with the 64-bit value 0x00000001.00000001.

When the load-latency facility is enabled, load operations are randomly selected by hardware and tagged to carry information related to data source locality and latency. Latency and data source information of tagged loads are updated internally.

When a PEBS assist occurs, the last update of latency and data source information are captured by the assist and written as part of the PEBS record. The PEBS sample after value (SAV), specified in PEBS CounterX Reset, operates orthogonally to the tagging mechanism. Loads are randomly tagged to collect latency data. The SAV

controls the number of tagged loads with latency information that will be written into the PEBS record field by the PEBS assists. The load latency data written to the PEBS record will be for the last tagged load operation which retired just before the PEBS assist was invoked.

The load-latency information written into a PEBS record (see Table 30-12, bytes AFH:98H) consists of:

- **Data Linear Address:** This is the linear address of the target of the load operation.
- **Latency Value:** This is the elapsed cycles of the tagged load operation between dispatch to GO, measured in processor core clock domain.
- **Data Source :** The encoded value indicates the origin of the data obtained by the load instruction. The encoding is shown in Table 30-13. In the descriptions local memory refers to system memory physically attached to a processor package, and remote memory referrals to system memory physically attached to another processor package.

**Table 30-13. Data Source Encoding for Load Latency Record**

| Encoding | Description                                                                                                                                                                                       |
|----------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0x0      | Unknown L3 cache miss                                                                                                                                                                             |
| 0x1      | Minimal latency core cache hit. This request was satisfied by the L1 data cache.                                                                                                                  |
| 0x2      | Pending core cache HIT. Outstanding core cache miss to same cache-line address was already underway.                                                                                              |
| 0x3      | This data request was satisfied by the L2.                                                                                                                                                        |
| 0x4      | L3 HIT. Local or Remote home requests that hit L3 cache in the uncore with no coherency actions required (snooping).                                                                              |
| 0x5      | L3 HIT. Local or Remote home requests that hit the L3 cache and was serviced by another processor core with a cross core snoop where no modified copies were found. (clean).                      |
| 0x6      | L3 HIT. Local or Remote home requests that hit the L3 cache and was serviced by another processor core with a cross core snoop where modified copies were found. (HITM).                          |
| 0x7      | Reserved                                                                                                                                                                                          |
| 0x8      | L3 MISS. Local homed requests that missed the L3 cache and was serviced by forwarded data following a cross package snoop where no modified copies found. (Remote home requests are not counted). |
| 0x9      | Reserved                                                                                                                                                                                          |
| 0xA      | L3 MISS. Local home requests that missed the L3 cache and was serviced by local DRAM (go to shared state).                                                                                        |

## PERFORMANCE MONITORING

Table 30-13. Data Source Encoding for Load Latency Record (Contd.)

| Encoding | Description                                                                                                     |
|----------|-----------------------------------------------------------------------------------------------------------------|
| 0xB      | L3 MISS. Remote home requests that missed the L3 cache and was serviced by remote DRAM (go to shared state).    |
| 0xC      | L3 MISS. Local home requests that missed the L3 cache and was serviced by local DRAM (go to exclusive state).   |
| 0xD      | L3 MISS. Remote home requests that missed the L3 cache and was serviced by remote DRAM (go to exclusive state). |
| 0xE      | I/O, Request of input/output operation                                                                          |
| 0xF      | The request was to un-cacheable memory.                                                                         |

The layout of MSR\_PEBS\_LD\_LAT\_THRESHOLD is shown in Figure 30-16.

Figure 30-16. Layout of MSR\_PEBS\_LD\_LAT MSR

Bits 15:0 specifies the threshold load latency in core clock cycles. Performance events with latencies greater than this value are counted in IA32\_PMCx and their latency information is reported in the PEBS record. Otherwise, they are ignored. The minimum value that may be programmed in this field is 3.

### 30.6.1.3 Off-core Response Performance Monitoring in the Processor Core

Performance an event using off-core response facility can program any of the four IA32\_PERFEVTSELx MSR with specific event codes and predefine mask bit value. Each event code for off-core response monitoring requires programming an associated configuration MSR, MSR\_OFFCORE\_RSP\_0. There is only one off-core response configuration MSR. Table 30-14 lists the event code, mask value and additional off-core configuration MSR that must be programmed to count off-core response events using IA32\_PMCx.

Table 30-14. Off-Core Response Event Encoding

| Event code in IA32_PERFEVTSELx | Mask Value in IA32_PERFEVTSELx | Required Off-core Response MSR    |
|--------------------------------|--------------------------------|-----------------------------------|
| 0xB7                           | 0x01                           | MSR_OFFCORE_RSP_0 (address 0x1A6) |

The layout of MSR\_OFFCORE\_RSP\_0 is shown in Figure 30-17. Bits 7:0 specifies the request type of a transaction request to the uncore. Bits 15:8 specifies the response of the uncore subsystem.

Figure 30-17. Layout of MSR\_OFFCORE\_RSP\_0 and MSR\_OFFCORE\_RSP\_1 to Configure Off-core Response Events

Table 30-15. MSR\_OFFCORE\_RSP\_0 and MSR\_OFFCORE\_RSP\_1 Bit Field Definition

| Bit Name     | Offset | Description                                                                                                                                                                                                           |
|--------------|--------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| DMND_DATA_RD | 0      | (R/W). Counts the number of demand and DCU prefetch data reads of full and partial cachelines as well as demand data page table entry cacheline reads. Does not count L2 data read prefetches or instruction fetches. |

## PERFORMANCE MONITORING

**Table 30-15. MSR\_OFFCORE\_RSP\_0 and MSR\_OFFCORE\_RSP\_1 Bit Field Definition**

| Bit Name            | Offset | Description                                                                                                                                                                                             |
|---------------------|--------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| DMND_RFO            | 1      | (R/W). Counts the number of demand and DCU prefetch reads for ownership (RFO) requests generated by a write to data cacheline. Does not count L2 RFO.                                                   |
| DMND_IFETCH         | 2      | (R/W). Counts the number of demand and DCU prefetch instruction cacheline reads. Does not count L2 code read prefetches.                                                                                |
| WB                  | 3      | (R/W). Counts the number of writeback (modified to exclusive) transactions.                                                                                                                             |
| PF_DATA_RD          | 4      | (R/W). Counts the number of data cacheline reads generated by L2 prefetchers.                                                                                                                           |
| PF_RFO              | 5      | (R/W). Counts the number of RFO requests generated by L2 prefetchers.                                                                                                                                   |
| PF_IFETCH           | 6      | (R/W). Counts the number of code reads generated by L2 prefetchers.                                                                                                                                     |
| OTHER               | 7      | (R/W). Counts one of the following transaction types, including L3 invalidate, I/O, full or partial writes, WC or non-temporal stores, CLFLUSH, Fences, lock, unlock, split lock.                       |
| UNCORE_HIT          | 8      | (R/W). L3 Hit: local or remote home requests that hit L3 cache in the uncore with no coherency actions required (snooping).                                                                             |
| OTHER_CORE_HI_T_SNP | 9      | (R/W). L3 Hit: local or remote home requests that hit L3 cache in the uncore and was serviced by another core with a cross core snoop where no modified copies were found (clean).                      |
| OTHER_CORE_HI_TM    | 10     | (R/W). L3 Hit: local or remote home requests that hit L3 cache in the uncore and was serviced by another core with a cross core snoop where modified copies were found (HTM).                           |
| Reserved            | 11     | Reserved                                                                                                                                                                                                |
| REMOTE_CACHE_FWD    | 12     | (R/W). L3 Miss: local homed requests that missed the L3 cache and was serviced by forwarded data following a cross package snoop where no modified copies found. (Remote home requests are not counted) |
| REMOTE_DRAM         | 13     | (R/W). L3 Miss: remote home requests that missed the L3 cache and were serviced by remote DRAM.                                                                                                         |
| LOCAL_DRAM          | 14     | (R/W). L3 Miss: local home requests that missed the L3 cache and were serviced by local DRAM.                                                                                                           |
| NON_DRAM            | 15     | (R/W). Non-DRAM requests that were serviced by IOH.                                                                                                                                                     |

### 30.6.2 Performance Monitoring Facility in the Uncore

The “uncore” in Intel microarchitecture code name Nehalem refers to subsystems in the physical processor package that are shared by multiple processor cores. Some of the sub-systems in the uncore include the L3 cache, Intel QuickPath Interconnect link logic, and integrated memory controller. The performance monitoring facilities inside the uncore operates in the same clock domain as the uncore (U-clock domain), which is usually different from the processor core clock domain. The uncore performance monitoring facilities described in this section apply to Intel Xeon processor 5500 series and processors with the following CPUID signatures: 06\_1AH, 06\_1EH, 06\_1FH (see Appendix B). An overview of the uncore performance monitoring facilities is described separately.

The performance monitoring facilities available in the U-clock domain consist of:

- Eight General-purpose counters (MSR\_UNCORE\_PerfCntr0 through MSR\_UNCORE\_PerfCntr7). The counters are 48 bits wide. Each counter is associated with a configuration MSR, MSR\_UNCORE\_PerfEvtSelx, to specify event code, event mask and other event qualification fields. A set of global uncore performance counter enabling/overflow/status control MSRs are also provided for software.
- Performance monitoring in the uncore provides an address/opcode match MSR that provides event qualification control based on address value or QPI command opcode.
- One fixed-function counter, MSR\_UNCORE\_FixedCntr0. The fixed-function uncore counter increments at the rate of the U-clock when enabled.

The frequency of the uncore clock domain can be determined from the uncore clock ratio which is available in the PCI configuration space register at offset COH under device number 0 and Function 0.

#### 30.6.2.1 Uncore Performance Monitoring Management Facility

MSR\_UNCORE\_PERF\_GLOBAL\_CTRL provides bit fields to enable/disable general-purpose and fixed-function counters in the uncore. Figure 30-18 shows the layout of MSR\_UNCORE\_PERF\_GLOBAL\_CTRL for an uncore that is shared by four processor cores in a physical package.

- EN\_PCn (bit n, n = 0, 7): When set, enables counting for the general-purpose uncore counter MSR\_UNCORE\_PerfCntr n.
- EN\_FCO (bit 32): When set, enables counting for the fixed-function uncore counter MSR\_UNCORE\_FixedCntr0.
- EN\_PMI\_COREn (bit n, n = 0, 3 if four cores are present): When set, processor core n is programmed to receive an interrupt signal from any interrupt enabled uncore counter. PMI delivery due to an uncore counter overflow is enabled by setting IA32\_DEBUG\_CTL.Offcore\_PMI\_EN to 1.
- PMI\_FRZ (bit 63): When set, all U-clock uncore counters are disabled when any one of them signals a performance interrupt. Software must explicitly re-enable

## PERFORMANCE MONITORING

the counter by setting the enable bits in MSR\_UNCORE\_PERF\_GLOBAL\_CTRL upon exit from the ISR.

Figure 30-18. Layout of MSR\_UNCORE\_PERF\_GLOBAL\_CTRL MSR

MSR\_UNCORE\_PERF\_GLOBAL\_STATUS provides overflow status of the U-clock performance counters in the uncore. This is a read-only register. If an overflow status bit is set the corresponding counter has overflowed. The register provides a condition change bit (bit 63) which can be quickly checked by software to determine if a significant change has occurred since the last time the condition change status was cleared. Figure 30-19 shows the layout of MSR\_UNCORE\_PERF\_GLOBAL\_STATUS.

- OVF\_PCr (bit n, n = 0, 7): When set, indicates general-purpose uncore counter MSR\_UNCORE\_PerfCntr n has overflowed.
- OVF\_FC0 (bit 32): When set, indicates the fixed-function uncore counter MSR\_UNCORE\_FixedCntr0 has overflowed.
- OVF\_PMI (bit 61): When set indicates that an uncore counter overflowed and generated an interrupt request.
- CHG (bit 63): When set indicates that at least one status bit in MSR\_UNCORE\_PERF\_GLOBAL\_STATUS register has changed state.

MSR\_UNCORE\_PERF\_GLOBAL\_OVF\_CTRL allows software to clear the status bits in the UNCORE\_PERF\_GLOBAL\_STATUS register. This is a write-only register, and individual status bits in the global status register are cleared by writing a binary one to the corresponding bit in this register. Writing zero to any bit position in this register has no effect on the uncore PMU hardware.

Figure 30-19. Layout of MSR\_UNCORE\_PERF\_GLOBAL\_STATUS MSR

Figure 30-20 shows the layout of MSR\_UNCORE\_PERF\_GLOBAL\_OVF\_CTRL.

Figure 30-20. Layout of MSR\_UNCORE\_PERF\_GLOBAL\_OVF\_CTRL MSR

## PERFORMANCE MONITORING

- CLR\_OVF\_PCr (bit n, n = 0, 7): Set this bit to clear the overflow status for general-purpose uncore counter MSR\_UNCORE\_PerfCntr n. Writing a value other than 1 is ignored.
- CLR\_OVF\_FCO (bit 32): Set this bit to clear the overflow status for the fixed-function uncore counter MSR\_UNCORE\_FixedCntr0. Writing a value other than 1 is ignored.
- CLR\_OVF\_PMI (bit 61): Set this bit to clear the OVF\_PMI flag in MSR\_UNCORE\_PERF\_GLOBAL\_STATUS. Writing a value other than 1 is ignored.
- CLR\_CHG (bit 63): Set this bit to clear the CHG flag in MSR\_UNCORE\_PERF\_GLOBAL\_STATUS register. Writing a value other than 1 is ignored.

### 30.6.2.2 Uncore Performance Event Configuration Facility

MSR\_UNCORE\_PerfEvtSel0 through MSR\_UNCORE\_PerfEvtSel7 are used to select performance event and configure the counting behavior of the respective uncore performance counter. Each uncore PerfEvtSel MSR is paired with an uncore performance counter. Each uncore counter must be locally configured using the corresponding MSR\_UNCORE\_PerfEvtSelx and counting must be enabled using the respective EN\_PCx bit in MSR\_UNCORE\_PERF\_GLOBAL\_CTRL. Figure 30-21 shows the layout of MSR\_UNCORE\_PERFEVTSELx.

Figure 30-21. Layout of MSR\_UNCORE\_PERFEVTSELx MSRs

- Event Select (bits 7:0): Selects the event logic unit used to detect uncore events.
- Unit Mask (bits 15:8) : Condition qualifiers for the event selection logic specified in the Event Select field.
- OCC\_CTR\_RST (bit17): When set causes the queue occupancy counter associated with this event to be cleared (zeroed). Writing a zero to this bit will be ignored. It will always read as a zero.

- Edge Detect (bit 18): When set causes the counter to increment when a deasserted to asserted transition occurs for the conditions that can be expressed by any of the fields in this register.
- PMI (bit 20): When set, the uncore will generate an interrupt request when this counter overflowed. This request will be routed to the logical processors as enabled in the PMI enable bits (EN\_PMI\_COREx) in the register MSR\_UNCORE\_PERF\_GLOBAL\_CTRL.
- EN (bit 22): When clear, this counter is locally disabled. When set, this counter is locally enabled and counting starts when the corresponding EN\_PCx bit in MSR\_UNCORE\_PERF\_GLOBAL\_CTRL is set.
- INV (bit 23): When clear, the Counter Mask field is interpreted as greater than or equal to. When set, the Counter Mask field is interpreted as less than.
- Counter Mask (bits 31:24): When this field is clear, it has no effect on counting. When set to a value other than zero, the logical processor compares this field to the event counts on each core clock cycle. If INV is clear and the event counts are greater than or equal to this field, the counter is incremented by one. If INV is set and the event counts are less than this field, the counter is incremented by one. Otherwise the counter is not incremented.

Figure 30-22 shows the layout of MSR\_UNCORE\_FIXED\_CTR\_CTRL.

Figure 30-22. Layout of MSR\_UNCORE\_FIXED\_CTR\_CTRL MSR

- EN (bit 0): When clear, the uncore fixed-function counter is locally disabled. When set, it is locally enabled and counting starts when the EN\_FCO bit in MSR\_UNCORE\_PERF\_GLOBAL\_CTRL is set.
- PMI (bit 2): When set, the uncore will generate an interrupt request when the uncore fixed-function counter overflowed. This request will be routed to the logical processors as enabled in the PMI enable bits (EN\_PMI\_COREx) in the register MSR\_UNCORE\_PERF\_GLOBAL\_CTRL.

Both the general-purpose counters (MSR\_UNCORE\_PerfCntr) and the fixed-function counter (MSR\_UNCORE\_FixedCntr0) are 48 bits wide. They support both counting

## PERFORMANCE MONITORING

and sampling usages. The event logic unit can filter event counts to specific regions of code or transaction types incoming to the home node logic.

### 30.6.2.3 Uncore Address/Opcode Match MSR

The Event Select field [7:0] of MSR\_UNCORE\_PERFEVTSELx is used to select different uncore event logic unit. When the event "ADDR\_OPCODE\_MATCH" is selected in the Event Select field, software can filter uncore performance events according to transaction address and certain transaction responses. The address filter and transaction response filtering requires the use of MSR\_UNCORE\_ADDR\_OPCODE\_MATCH register. The layout is shown in Figure 30-23.

Figure 30-23. Layout of MSR\_UNCORE\_ADDR\_OPCODE\_MATCH MSR

- Addr (bits 39:3): The physical address to match if "MatchSel" field is set to select address match. The uncore performance counter will increment if the lowest 40-bit incoming physical address (excluding bits 2:0) for a transaction request matches bits 39:3.
- Opcode (bits 47:40) : Bits 47:40 allow software to filter uncore transactions based on QPI link message class/packed header opcode. These bits are consists two sub-fields:
  - Bits 43:40 specify the QPI packet header opcode,
  - Bits 47:44 specify the QPI message classes.

Table 30-16 lists the encodings supported in the opcode field.

Table 30-16. Opcode Field Encoding for MSR\_UNCORE\_ADDR\_OPCODE\_MATCH

| Opcode [43:40] | QPI Message Class               |                                   |                                  |
|----------------|---------------------------------|-----------------------------------|----------------------------------|
|                | Home Request<br>[47:44] = 0000B | Snoop Response<br>[47:44] = 0001B | Data Response<br>[47:44] = 1110B |

Table 30-16. Opcode Field Encoding for MSR\_UNCORE\_ADDR\_OPCODE\_MATCH

| Opcode [43:40] | QPI Message Class |    |  |
|----------------|-------------------|----|--|
|                |                   | 1  |  |
| DMND_IFETCH    | 2                 | 2  |  |
| WB             | 3                 | 3  |  |
| PF_DATA_RD     | 4                 | 4  |  |
| PF_RFO         | 5                 | 5  |  |
| PF_IFETCH      | 6                 | 6  |  |
| OTHER          | 7                 | 7  |  |
| NON_DRAM       | 15                | 15 |  |

- MatchSel (bits 63:61): Software specifies the match criteria according to the following encoding:
  - 000B: Disable addr\_opcode match hardware
  - 100B: Count if only the address field matches,
  - 010B: Count if only the opcode field matches
  - 110B: Count if either opcode field matches or the address field matches
  - 001B: Count only if both opcode and address field match
  - Other encoding are reserved

### 30.6.3 Intel Xeon Processor 7500 Series Performance Monitoring Facility

The performance monitoring facility in the processor core of Intel Xeon processor 7500 series are the same as those supported in Intel Xeon processor 5500 series. The uncore subsystem in Intel Xeon processor 7500 series are significantly different. The uncore performance monitoring facility consist of many distributed units associated with individual logic control units (referred to as boxes) within the uncore subsystem. A high level block diagram of the various box units of the uncore is shown in Figure 30-24.

Uncore PMUs are programmed via MSR interfaces. Each of the distributed uncore PMU units have several general-purpose counters. Each counter requires an associated event select MSR, and may require additional MSRs to configure sub-event conditions. The uncore PMU MSRs associated with each box can be categorized based on its functional scope: per-counter, per-box, or global across the uncore. The number counters available in each box type are different. Each box generally provides a set of MSRs to enable/disable, check status/overflow of multiple counters within each box.

## PERFORMANCE MONITORING

Figure 30-24. Distributed Units of the Uncore of Intel Xeon Processor 7500 Series

Table 30-17 summarizes the number MSRs for uncore PMU for each box.

Table 30-17. Uncore PMU MSR Summary

| Box   | # of Boxes | Counters per Box         | Counter Width | General Purpose | Global Enable | Sub-control MSRs |
|-------|------------|--------------------------|---------------|-----------------|---------------|------------------|
| C-Box | 8          | 6                        | 48            | Yes             | per-box       | None             |
| S-Box | 2          | 4                        | 48            | Yes             | per-box       | Match/Mask       |
| B-Box | 2          | 4                        | 48            | Yes             | per-box       | Match/Mask       |
| M-Box | 2          | 6                        | 48            | Yes             | per-box       | Yes              |
| R-Box | 1          | 16 ( 2 port, 8 per port) | 48            | Yes             | per-box       | Yes              |
| W-Box | 1          | 4                        | 48            | Yes             | per-box       | None             |
|       |            | 1                        | 48            | No              | per-box       | None             |
| U-Box | 1          | 1                        | 48            | Yes             | uncore        | None             |

The W-Box provides 4 general-purpose counters, each requiring an event select configuration MSR, similar to the general-purpose counters in other boxes. There is also a fixed-function counter that increments clockticks in the uncore clock domain.

For C,S,B,M,R, and W boxes, each box provides an MSR to enable/disable counting, configuring PMI of multiple counters within the same box, this is somewhat similar the “global control” programming interface, IA32\_PERF\_GLOBAL\_CTRL, offered in the core PMU. Similarly status information and counter overflow control for multiple counters within the same box are also provided in C,S,B,M,R, and W boxes.

In the U-Box, MSR\_U\_PMON\_GLOBAL\_CTRL provides overall uncore PMU enable/disable and PMI configuration control. The scope of status information in the U-box is at per-box granularity, in contrast to the per-box status information MSR (in the C,S,B,M,R, and W boxes) providing status information of individual counter overflow. The difference in scope also apply to the overflow control MSR in the U-Box versus those in the other Boxes.

The individual MSRs that provide uncore PMU interfaces are listed in Appendix B.

Table B-7 under the general naming style of

MSR\_%box#%\_PMON\_%scope\_function%, where %box#% designates the type of box and zero-based index if there are more than one box of the same type, %scope\_function% follows the examples below:

- Multi-counter enabling MSRs: MSR\_U\_PMON\_GLOBAL\_CTL, MSR\_S0\_PMON\_BOX\_CTL, MSR\_C7\_PMON\_BOX\_CTL, etc.
- Multi-counter status MSRs: MSR\_U\_PMON\_GLOBAL\_STATUS, MSR\_S0\_PMON\_BOX\_STATUS, MSR\_C7\_PMON\_BOX\_STATUS, etc.
- Multi-counter overflow control MSRs: MSR\_U\_PMON\_GLOBAL\_OVF\_CTL, MSR\_S0\_PMON\_BOX\_OVF\_CTL, MSR\_C7\_PMON\_BOX\_OVF\_CTL, etc.
- Performance counters MSRs: the scope is implicitly per counter, e.g. MSR\_U\_PMON\_CTR, MSR\_S0\_PMON\_CTR0, MSR\_C7\_PMON\_CTR5, etc
- Event select MSRs: the scope is implicitly per counter, e.g. MSR\_U\_PMON\_EVNT\_SEL, MSR\_S0\_PMON\_EVNT\_SEL0, MSR\_C7\_PMON\_EVNT\_SEL5, etc
- Sub-control MSRs: the scope is implicitly per-box granularity, e.g. MSR\_M0\_PMON\_TIMESTAMP, MSR\_R0\_PMON\_IPERF0\_P1, MSR\_S1\_PMON\_MATCH.

Details of uncore PMU MSR bit field definitions can be found in a separate document “Intel Xeon Processor 7500 Series Uncore Performance Monitoring Guide”.

## 30.7 PERFORMANCE MONITORING FOR PROCESSORS BASED ON INTEL® MICROARCHITECTURE CODE NAME WESTMERE

All of the performance monitoring programming interfaces (architectural and non-architectural core PMU facilities, and uncore PMU) described in Section 30.6 also apply to processors based on Intel® microarchitecture code name Westmere.

Table 30-14 describes a non-architectural performance monitoring event (event code 0B7H) and associated MSR\_OFFCORE\_RSP\_0 (address 1A6H) in the core PMU. This event and a second functionally equivalent offcore response event using event code 0BBH and MSR\_OFFCORE\_RSP\_1 (address 1A7H) are supported in processors based on Intel microarchitecture code name Westmere. The event code and event mask definitions of Non-architectural performance monitoring events are listed in Table A-11.

The load latency facility is the same as described in Section 30.6.1.2, but added enhancement to provide more information in the data source encoding field of each load latency record. The additional information relates to STLB\_MISS and LOCK, see Table 30-22.

### 30.7.1 Intel Xeon Processor E7 Family Performance Monitoring Facility

The performance monitoring facility in the processor core of the Intel Xeon processor E7 family is the same as those supported in the Intel Xeon processor 5600 series<sup>2</sup>. The uncore subsystem in the Intel Xeon processor E7 family is similar to those of the Intel Xeon processor 7500 series. The high level construction of the uncore subsystem is similar to that shown in Figure 30-24, with the additional capability that up to 10 C-Box units are supported.

Table 30-18 summarizes the number MSRs for uncore PMU for each box.

**Table 30-18. Uncore PMU MSR Summary for Intel Xeon Processor E7 Family**

| Box   | # of Boxes | Counters per Box | Counter Width | General Purpose | Global Enable | Sub-control MSRs |
|-------|------------|------------------|---------------|-----------------|---------------|------------------|
| C-Box | 10         | 6                | 48            | Yes             | per-box       | None             |
| S-Box | 2          | 4                | 48            | Yes             | per-box       | Match/Mask       |
| B-Box | 2          | 4                | 48            | Yes             | per-box       | Match/Mask       |
| M-Box | 2          | 6                | 48            | Yes             | per-box       | Yes              |

2. Exceptions are indicated for event code 0FH in Table A-6; and valid bits of data source encoding field of each load latency record is limited to bits 5:4 of Table 30-22.

Table 30-18. Uncore PMU MSR Summary for Intel Xeon Processor E7 Family

| Box   | # of Boxes | Counters per Box         | Counter Width | General Purpose | Global Enable | Sub-control MSRs |
|-------|------------|--------------------------|---------------|-----------------|---------------|------------------|
| R-Box | 1          | 16 ( 2 port, 8 per port) | 48            | Yes             | per-box       | Yes              |
| W-Box | 1          | 4                        | 48            | Yes             | per-box       | None             |
|       |            | 1                        | 48            | No              | per-box       | None             |
| U-Box | 1          | 1                        | 48            | Yes             | uncore        | None             |

## 30.8 PERFORMANCE MONITORING FOR PROCESSORS BASED ON INTEL® MICROARCHITECTURE CODE NAME SANDY BRIDGE

Intel Core i7, i5, i3 processors 2xxx series are based on Intel microarchitecture code name Sandy Bridge, this section describes the performance monitoring facilities provided in the processor core. The core PMU supports architectural performance monitoring capability with version ID 3 (see Section 30.2.2.2) and a host of non-architectural monitoring capabilities.

Architectural performance monitoring events and non-architectural monitoring events are programmed using fixed counters and programmable counters/event select MSRs described in Section 30.2.2.2.

The core PMU's capability is similar to those described in Section 30.6.1 and Section 30.7, with some differences and enhancements relative to Intel microarchitecture code name Westmere summarized in Table 30-19.

Table 30-19. Core PMU Comparison

| Box                                    | Sandy Bridge                                 | Westmere        | Comment                                  |
|----------------------------------------|----------------------------------------------|-----------------|------------------------------------------|
| # of Fixed counters per thread         | 3                                            | 3               | Use CPUID to enumerate # of counters     |
| # of general-purpose counters per core | 8                                            | 8               |                                          |
| Counter width (R,W)                    | R:48 , W: 32/48                              | R:48, W:32      | see Section 30.2.2.3                     |
| # of programmable counters per thread  | 4 or (8 if a core not shared by two threads) | 4               | Use CPUID to enumerate # of counters     |
| PEBS Events                            | See Table 30-21                              | See Table 30-10 | IA32_PMC4-IA32_PMC7 do not support PEBS. |

Table 30-19. Core PMU Comparison

| Box                     | Sandy Bridge                                           | Westmere                         | Comment                     |
|-------------------------|--------------------------------------------------------|----------------------------------|-----------------------------|
| PEBS-Load Latency       | Data source/ STLB/Lock encoding; See Section 30.8.4.2  | Data source encoding             |                             |
| PEBS-Precise Store      | Section 30.8.4.3                                       | No                               |                             |
| PEBS-PDIR               | yes (using precise INST_RETIRE_ALL)                    | No PDIR, no INST_RETIRE_ALL      |                             |
| Off-core Response Event | MSR 1A6H and 1A7H; Extended request and response types | MSR 1A6H and 1A7H, limited types | Nehalem supports 1A6H only. |

### 30.8.1 Global Counter Control Facilities In Intel® microarchitecture code name Sandy Bridge

The number of general-purpose performance counters visible to a logical processor can vary across Processors based on Intel microarchitecture code name Sandy Bridge. Software must use CPUID to determine the number performance counters/event select registers (See Section 30.2.1.1).

Figure 30-25. IA32\_PERF\_GLOBAL\_CTRL MSR in Intel microarchitecture code name Sandy Bridge

Figure 30-10 depicts the layout of IA32\_PERF\_GLOBAL\_CTRL MSR. The enable bits (PMC4\_EN, PMC5\_EN, PMC6\_EN, PMC7\_EN) corresponding to IA32\_PMC4-

IA32\_PMC7 are valid only if CPUID.0AH:EAX[15:8] reports a value of '8'. If CPUID.0AH:EAX[15:8] = 4, attempts to set the invalid bits will cause #GP.

Each enable bit in IA32\_PERF\_GLOBAL\_CTRL is AND'ed with the enable bits for all privilege levels in the respective IA32\_PERFEVTSELx or IA32\_PERF\_FIXED\_CTR\_CTRL MSRs to start/stop the counting of respective counters. Counting is enabled if the AND'ed results is true; counting is disabled when the result is false.

IA32\_PERF\_GLOBAL\_STATUS MSR provides single-bit status used by software to query the overflow condition of each performance counter. The MSR also provides additional status bit to indicate overflow conditions when counters are programmed for precise-event-based sampling (PEBS). The IA32\_PERF\_GLOBAL\_STATUS MSR also provides a 'sticky bit' to indicate changes to the state of performance monitoring hardware (see Figure 30-26). A value of 1 in each bit of the PMCx\_OVF field indicates an overflow condition has occurred in the associated counter.

Figure 30-26. IA32\_PERF\_GLOBAL\_STATUS MSR in Intel microarchitecture code name Sandy Bridge

When a performance counter is configured for PEBS, an overflow condition in the counter generates a performance-monitoring interrupt this signals a PEBS event. On a PEBS event, the processor stores data records in the buffer area (see Section 16.4.9), clears the counter overflow status, and sets the OvfBuffer bit in IA32\_PERF\_GLOBAL\_STATUS.

IA32\_PERF\_GLOBAL\_OVF\_CTL MSR allows software to clear overflow the indicators for general-purpose or fixed-function counters via a single WRMSR (see Figure 30-27). Clear overflow indications when:

## PERFORMANCE MONITORING

- Setting up new values in the event select and/or UMASK field for counting or sampling
- Reloading counter values to continue sampling
- Disabling event counting or sampling

Figure 30-27. IA32\_PERF\_GLOBAL\_OVF\_CTRL MSR in Intel microarchitecture code name Sandy Bridge

### 30.8.2 Counter Coalescence

In processors based on Intel microarchitecture code name Sandy Bridge, each processor core implements eight general-purpose counters. CPUID.0AH:EAX[15:8] will report either 4 or 8 depending specific processor's product features.

If a processor core is shared by two logical processors, each logical processors can access 4 counters (IA32\_PMC0-IA32\_PMC3). This is the same as in the prior generation for processors based on Intel microarchitecture code name Nehalem.

If a processor core is not shared by two logical processors, all eight general-purpose counters are visible, and CPUID.0AH:EAX[15:8] reports 8. IA32\_PMC4-IA32\_PMC7 occupy MSR addresses 0C5H through 0C8H. Each counter is accompanied by an event select MSR (IA32\_PERFEVTSEL4-IA32\_PERFEVTSEL7).

If CPUID.0AH:EAX[15:8] report 4, access to IA32\_PMC4-IA32\_PMC7, IA32\_PMC4-IA32\_PMC7 will cause #GP. Writing 1's to bit position 7:4 of IA32\_PERF\_GLOBAL\_CTRL, IA32\_PERF\_GLOBAL\_STATUS, or IA32\_PERF\_GLOBAL\_OVF\_CTL will also cause #GP.

### 30.8.3 Full Width Writes to Performance Counters

Processors based on Intel microarchitecture code name Sandy Bridge support full-width writes to the general-purpose counters, IA32\_PMCx. Support of full-width writes are enumerated by IA32\_PERF\_CAPABILITIES.FW\_WRITES[13] (see Section 30.2.2.3).

The default behavior of IA32\_PMCx is unchanged, i.e. WRMSR to IA32\_PMCx results in a sign-extended 32-bit value of the input EAX written into IA32\_PMCx. Full-width writes must issue WRMSR to a dedicated alias MSR address for each IA32\_PMCx.

Software must check the presence of full-width write capability and the presence of the alias address IA32\_A\_PMCx by testing IA32\_PERF\_CAPABILITIES[13].

### 30.8.4 PEBS Support in Intel® microarchitecture code name Sandy Bridge

Processors based on Intel microarchitecture code name Sandy Bridge support PEBS, similar to those offered in prior generation, with several enhanced features. The key components and differences of PEBS facility relative to Intel microarchitecture code name Westmere is summarized in Table 30-20.

Table 30-20. PEBS Facility Comparison

| Box                     | Sandy Bridge                                                            | Westmere         | Comment                                  |

Only IA32\_PMCO through IA32\_PMC3 support PEBS.

## PERFORMANCE MONITORING

### NOTE

PEBS events are only valid when the following fields of IA32\_PERFEVTSELx are all zero: AnyThread, Edge, Invert, CMask.

In IA32\_PEBS\_ENABLE MSR, bit 63 is defined as PS\_ENABLE: When set, this enables IA32\_PMC3 to capture precise store information. Only IA32\_PMC3 supports the precise store facility.

Figure 30-28. Layout of IA32\_PEBS\_ENABLE MSR

#### 30.8.4.1 PEBS Record Format

The layout of PEBS records physically identical to those shown in Table 30-12, but the fields at offset 98H, A0H and A8H have been enhanced to support additional PEBS capabilities.

- Load/Store Data Linear Address (Offset 98H): This field will contain the linear address of the source of the load, or linear address of the destination of the store.
- Data Source /Store Status (Offset A0H): When load latency is enabled, this field will contain three piece of information (including an encoded value indicating the source which satisfied the load operation). The source field encodings are detailed in Table 30-13. When precise store is enabled, this field will contain information indicating the status of the store, as detailed in Table 19.
- Latency Value/0 (Offset A8H): When load latency is enabled, this field contains the latency in cycles to service the load. This field is not meaningful when precise store is enabled and will be written to zero in that case. Upon writing the PEBS record, microcode clears the overflow status bits in the IA32\_PERF\_GLOBAL\_STATUS corresponding to those counters that both

overflowed and were enabled in the IA32\_PEBS\_ENABLE register. The status bits of other counters remain unaffected.

The number PEBS events has expanded. The list of PEBS events supported in Intel microarchitecture code name Sandy Bridge is shown in Table 30-21.

**Table 30-21. PEBS Performance Events for Intel microarchitecture code name Sandy Bridge**

| Event Name           | Event Select | Sub-event     | UMask            |
|----------------------|--------------|---------------|------------------|
| INST_RETIRE          | COH          | PREC_DIST     | 01H <sup>1</sup> |
| UOPS_RETIRE          | C2H          | All           | 01H              |
|                      |              | Retire_Slots  | 02H              |

| Event Name                    | Event Select | Sub-event | UMask |
|-------------------------------|--------------|-----------|-------|
| MEM_LOAD_UOPS_LLC_HIT_RETIRED | D2H          | XSNP_Miss | 01H   |
|                               |              | XSNP_Hit  | 02H   |
|                               |              | XSNP_Hitm | 04H   |
|                               |              | XSNP_None | 08H   |
| MEM_LOAD_UOPS_MISC_RETIRED    | D4H          | LLC_Miss  | 02H   |

**NOTES:**

1. Only available on IA32\_PMC1.

### 30.8.4.2 Load Latency Performance Monitoring Facility

The load latency facility in Intel microarchitecture code name Sandy Bridge is similar to that in prior microarchitecture. It provides software a means to characterize the average load latency to different levels of cache/memory hierarchy. This facility requires processor supporting enhanced PEBS record format in the PEBS buffer, see Table 30-12 and Section 30.8.4.1. The facility measures latency from micro-operation (uop) dispatch to when data is globally observable (GO).

To use this feature software must assure:

- One of the IA32\_PERFEVTSELx MSR is programmed to specify the event unit MEM\_TRANS\_RETIRED, and the LATENCY ABOVE THRESHOLD event mask must be specified (IA32\_PerfEvtSelX[15:0] = 0x1CDH). The corresponding counter IA32\_PMCx will accumulate event counts for architecturally visible loads which exceed the programmed latency threshold specified separately in a MSR. Stores are ignored when this event is programmed. The CMASK or INV fields of the IA32\_PerfEvtSelX register used for counting load latency must be 0. Writing other values will result in undefined behavior.
- The MSR\_PEBS\_LD\_LAT\_THRESHOLD MSR is programmed with the desired latency threshold in core clock cycles. Loads with latencies greater than this value are eligible for counting and latency data reporting. The minimum value that may be programmed in this register is 3 (the minimum detectable load latency is 4 core clock cycles).
- The PEBS enable bit in the IA32\_PEBS\_ENABLE register is set for the corresponding IA32\_PMCx counter register. This means that both the PEBS\_EN\_CTRX and LL\_EN\_CTRX bits must be set for the counter(s) of interest. For example, to enable load latency on counter IA32\_PMC0, the IA32\_PEBS\_ENABLE register must be programmed with the 64-bit value 0x00000001.00000001.
- When Load latency event is enabled, no other PEBS event can be configured with other counters.

When the load-latency facility is enabled, load operations are randomly selected by hardware and tagged to carry information related to data source locality and latency. Latency and data source information of tagged loads are updated internally. The MEM\_TRANS\_RETIRED event for load latency counts only tagged retired loads. If a load is cancelled it will not be counted and the internal state of the load latency facility will not be updated. In this case the hardware will tag the next available load.

When a PEBS assist occurs, the last update of latency and data source information are captured by the assist and written as part of the PEBS record. The PEBS sample after value (SAV), specified in PEBS CounterX Reset, operates orthogonally to the tagging mechanism. Loads are randomly tagged to collect latency data. The SAV controls the number of tagged loads with latency information that will be written into the PEBS record field by the PEBS assists. The load latency data written to the PEBS record will be for the last tagged load operation which retired just before the PEBS assist was invoked.

The physical layout of the PEBS records is the same as shown in Table 30-12. The specificity of Data Source entry at offset A0H has been enhanced to report three piece of information.

**Table 30-22. Layout of Data Source Field of Load Latency Record**

| Field     | Position | Description                                                                                        |
|-----------|----------|----------------------------------------------------------------------------------------------------|
| Source    | 3:0      | See Table 30-13                                                                                    |
| STLB_MISS | 4        | 0: The load did not miss the STLB (hit the DTLB or STLB).<br>1: The load missed the STLB.          |
| Lock      | 5        | 0: The load was not part of a locked transaction.<br>1: The load was part of a locked transaction. |
| Reserved  | 63:6     |                                                                                                    |

The layout of MSR\_PEBS\_LD\_LAT\_THRESHOLD is the same as shown in Figure 30-16.

### 30.8.4.3 Precise Store Facility

Processors based on Intel microarchitecture code name Sandy Bridge offer a precise store capability that complements the load latency facility. It provides a means to profile store memory references in the system.

Precise stores leverage the PEBS facility and provide additional information about sampled stores. Having precise memory reference events with linear address information for both loads and stores can help programmers improve data structure layout, eliminate remote node references, and identify cache-line conflicts in NUMA systems.

## PERFORMANCE MONITORING

Only IA32\_PMC3 can be used to capture precise store information. After enabling this facility, counter overflows will initiate the generation of PEBS records as previously described in PEBS. Upon counter overflow hardware captures the linear address and other status information of the next store that retires. This information is then written to the PEBS record.

To enable the precise store facility, software must complete the following steps. Please note that the precise store facility relies on the PEBS facility, so the PEBS configuration requirements must be completed before attempting to capture precise store information.

- Complete the PEBS configuration steps.
- Program the MEM\_TRANS\_RETIRED.PRECISE\_STORE event in IA32\_PERFEVTSEL3. Only counter 3 (IA32\_PMC3) supports collection of precise store information.
- Set IA32\_PEBS\_ENABLE[3] and IA32\_PEBS\_ENABLE[63]. This enables IA32\_PMC3 as a PEBS counter and enables the precise store facility, respectively.

The precise store information written into a PEBS record affects entries at offset 98H, A0H and A8H of Table 30-12. The specificity of Data Source entry at offset A0H has been enhanced to report three piece of information.

**Table 30-23. Layout of Precise Store Information In PEBS Record**

| Field                     | Offset | Description                                                                                                                                                                                                                                                                                                                                                                                        |
|---------------------------|--------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Store Data Linear Address | 98H    | The linear address of the destination of the store.                                                                                                                                                                                                                                                                                                                                                |
| Store Status              | A0H    | <b>DCU Hit</b> (Bit 0): The store hit the data cache closest to the core (lowest latency cache) if this bit is set, otherwise the store missed the data cache.<br><b>STLB Miss</b> (bit 4): The store missed the STLB if set, otherwise the store hit the STLB<br><b>Locked Access</b> (bit 5): The store was part of a locked access if set, otherwise the store was not part of a locked access. |
| Reserved                  | A8H    | Reserved                                                                                                                                                                                                                                                                                                                                                                                           |

### 30.8.4.4 Precise Distribution of Instructions Retired (PDIR)

Upon triggering a PEBS assist, there will be a finite delay between the time the counter overflows and when the microcode starts to carry out its data collection obligations. INST\_RETIRED is a very common event that is used to sample where performance bottleneck happened and to help identify its location in instruction address space. Even if the delay is constant in core clock space, it invariably manifest as variable "skids" in instruction address space. This creates a challenge for programmers to profile a workload and pinpoint the location of bottlenecks.

The core PMU in processors based on Intel microarchitecture code name Sandy Bridge include a facility referred to as precise distribution of Instruction Retired (PDIR).

The PDIR facility mitigates the “skid” problem by providing an early indication of when the INST\_RETIRE counter is about to overflow, allowing the machine to more precisely trap on the instruction that actually caused the counter overflow thus eliminating skid.

PDIR applies only to the INST\_RETIRE.PREC\_DIST precise event, and must use IA32\_PMC1 with PerfEvtSel1 property configured and bit 1 in the IA32\_PEBS\_ENABLE set to 1. INST\_RETIRE.PREC\_DIST is a non-architectural performance event, it is not supported in prior generation microarchitectures. Additionally, current implementation of PDIR limits tool to quiesce the rest of the programmable counters in the core when PDIR is active.

### 30.8.5 Off-core Response Performance Monitoring

The core PMU in processors based on Intel microarchitecture code name Sandy Bridge provides off-core response facility similar to prior generation. Off-core response can be programmed only with a specific pair of event select and counter MSR, and with specific event codes and predefine mask bit value in a dedicated MSR to specify attributes of the off-core transaction. Two event codes are dedicated for off-core response event programming. Each event code for off-core response monitoring requires programming an associated configuration MSR, MSR\_OFFCORE\_RSP\_X. Table 30-24 lists the event code, mask value and additional off-core configuration MSR that must be programmed to count off-core response events using IA32\_PMCx.

Table 30-24. Off-Core Response Event Encoding

| Counter | Event code | UMask | Required Off-core Response MSR    |
|---------|------------|-------|-----------------------------------|
| PMC0    | 0xB7       | 0x01  | MSR_OFFCORE_RSP_0 (address 0x1A6) |
| PMC3    | 0xBB       | 0x01  | MSR_OFFCORE_RSP_1 (address 0x1A7) |

The layout of MSR\_OFFCORE\_RSP\_0 and MSR\_OFFCORE\_RSP\_1 are shown in Figure 30-29 and Figure 30-30. Bits 15:0 specifies the request type of a transaction request to the uncore. Bits 30:16 specifies supplier information, bits 37:31 specifies snoop response information.

## PERFORMANCE MONITORING

Figure 30-29. Request\_Type Fields for MSR\_OFFCORE\_RSP\_x

Table 30-25. MSR\_OFFCORE\_RSP\_x Request\_Type Field Definition

| Bit Name     | Offset | Description                                                                                                                                                                                                           |
|--------------|--------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| DMND_DATA_RD | 0      | (R/W). Counts the number of demand and DCU prefetch data reads of full and partial cachelines as well as demand data page table entry cacheline reads. Does not count L2 data read prefetches or instruction fetches. |
| DMND_RFO     | 1      | (R/W). Counts the number of demand and DCU prefetch reads for ownership (RFO) requests generated by a write to data cacheline. Does not count L2 RFO prefetches.                                                      |
| DMND_IFETCH  | 2      | (R/W). Counts the number of demand and DCU prefetch instruction cacheline reads. Does not count L2 code read prefetches.                                                                                              |
| WB           | 3      | (R/W). Counts the number of writeback (modified to exclusive) transactions.                                                                                                                                           |
| PF_DATA_RD   | 4      | (R/W). Counts the number of data cacheline reads generated by L2 prefetchers.                                                                                                                                         |
| PF_RFO       | 5      | (R/W). Counts the number of RFO requests generated by L2 prefetchers.                                                                                                                                                 |
| PF_IFETCH    | 6      | (R/W). Counts the number of code reads generated by L2 prefetchers.                                                                                                                                                   |

Table 30-25. MSR\_OFFCORE\_RSP\_x Request\_Type Field Definition (Contd.)

| Bit Name       | Offset | Description                                               |
|----------------|--------|-----------------------------------------------------------|
| PF_LLC_DATA_RD | 7      | (R/W). L2 prefetcher to L3 for loads.                     |
| PF_LLC_RFO     | 8      | (R/W). RFO requests generated by L2 prefetcher            |
| PF_LLC_IFETCH  | 9      | (R/W). L2 prefetcher to L3 for instruction fetches.       |
| BUS_LOCKS      | 10     | (R/W). Bus lock and split lock requests                   |
| STRM_ST        | 11     | (R/W). Streaming store requests                           |
| OTHER          | 15     | (R/W). Any other request that crosses IDI, including I/O. |

Figure 30-30. Response\_Type Fields for MSR\_OFFCORE\_RSP\_x

To properly program this extra register, software must set at least one request type bit and a valid response type pattern. Otherwise, the event count reported will be zero. It is permissible and useful to set multiple request and response type bits in order to obtain various classes of off-core response events.

Table 30-26. MSR\_OFFCORE\_RSP\_x Response Type Field Definition

| Subtype | Bit Name | Offset | Description                                    |
|---------|----------|--------|------------------------------------------------|
| Common  | Any      | 16     | (R/W). Catch all value for any response types. |

PERFORMANCE MONITORING

|               | SNP_MISS       | 33     | (R/W). A snoop was needed and it missed all snooped caches:<br>-For LLC Hit, ResHitl was returned by all cores<br>-For LLC Miss, RspI was returned by all sockets and data was returned from DRAM.                                                                                                                                                                         |
|               | SNP_NO_FWD     | 34     | (R/W). A snoop was needed and it hits in at least one snooped cache. Hit denotes a cache-line was valid before snoop effect. This includes:<br>-Snoop Hit w/ Invalidation (LLC Hit, RFO)<br>-Snoop Hit, Left Shared (LLC Hit/Miss, IFetch/Data_RD)<br>-Snoop Hit w/ Invalidation and No Forward (LLC Miss, RFO Hit S)<br>In the LLC Miss case, data is returned from DRAM. |
|               | SNP_FWD        | 35     | (R/W). A snoop was needed and data was forwarded from a remote socket. This includes:<br>-Snoop Forward Clean, Left Shared (LLC Hit/Miss, IFetch/Data_RD/RFT).                                                                                                                                                                                                             |
|               | HITM           | 36     | (R/W). A snoop was needed and it HitM-ed in local or remote cache. HitM denotes a cache-line was in modified state before effect as a result of snoop. This includes:<br>-Snoop HitM w/ WB (LLC miss, IFetch/Data_RD)<br>-Snoop Forward Modified w/ Invalidation (LLC Hit/Miss, RFO)<br>-Snoop MtoS (LLC Hit, IFetch/Data_RD).                                             |
|               | NON_DRAM       | 37     | (R/W). Target was non-DRAM system address. This includes MMIO transactions.                                                                                                                                                                                                                                                                                                |

To specify a complete offcore response filter, software must properly program bits in the request and response type fields. A valid request type must have at least one bit set in the non-reserved bits of 15:0. A valid response type must be a non-zero value of the following expression:

ANY | [('OR' of Supplier Info Bits) & ('OR' of Snoop Info Bits)]

If "ANY" bit is set, the supplier and snoop info bits are ignored.

### 30.8.6 Uncore Performance Monitoring Facilities In Intel® Core i7, i5, i3 Processors 2xxx Series

The uncore sub-system in Intel Core i7, i5, i3 processors 2xxx Series provides a unified L3 that can support up to four processor cores. The L3 cache consists multiple slices, each slice interface with a processor via a coherence engine, referred to as a C-Box. Each C-Box provides dedicated facility of MSRs to select uncore performance monitoring events and each C-Box event select MSR is paired with a counter register, similar in style as those described in Section 30.6.2.2. The layout of the event select MSRs in the C-Boxes are shown in Figure 30-31.

Figure 30-31. Layout of MSR\_UNC\_CBO\_N\_PERFEVTSELx MSR for C-Box N

At the uncore domain level, there is a master set of control MSRs that centrally manages all the performance monitoring facility of uncore units. Figure 30-32 shows the layout of the uncore domain global control

MSR bit 31 of MSR\_UNC\_PERF\_GLOBAL\_CTRL provides the capability to freeze all uncore counters when an overflow condition in a unit counter. When set and upon a counter overflow, the uncore PMU logic will clear the global enable bit, bit 29.

## PERFORMANCE MONITORING

Figure 30-32. Layout of MSR\_UNC\_PERF\_GLOBAL\_CTRL MSR for Uncore

Additionally, there is also a fixed counter, counting uncore clockticks, for the uncore domain. Table 30-27 summarizes the number MSRs for uncore PMU for each box.

Table 30-27. Uncore PMU MSR Summary

| Box   | # of Boxes | Counters per Box | Counter Width | General Purpose | Global Enable | Comment |
|-------|------------|------------------|---------------|-----------------|---------------|---------|
| C-Box | Up to 4    | 2                | 44            | Yes             | Per-box       |         |
| NCU   |            | 1                | 48            | No              | Uncore        |         |

### 30.8.6.1 Uncore Performance Monitoring Events

There are certain restrictions on the uncore performance counters in each C-Box. Specifically,

- Occupancy events are supported only with counter 0 but not counter 1.

Other uncore C-Box events can be programmed with either counter 0 or 1.

The C-Box uncore performance events described in Table A-3 can collect performance characteristics of transactions initiated by processor core. In that respect, they are similar to various sub-events in the OFFCORE\_RESPONSE family of performance events in the core PMU. Information such as data supplier locality (LLC HIT/MISS) and snoop responses can be collected via OFFCORE\_RESPONSE and qualified on a per-thread basis.

On the other hand, uncore performance event logic can not associate its counts with the same level of per-thread qualification attributes as the core PMU events can. Therefore, whenever similar event programming capabilities are available from both

core PMU and uncore PMU, the recommendation is that utilizing the core PMU events may be less affected by artifacts, complex interactions and other factors.

## 30.9 PERFORMANCE MONITORING (PROCESSORS BASED ON INTEL NETBURST® MICROARCHITECTURE)

The performance monitoring mechanism provided in Pentium 4 and Intel Xeon processors is different from that provided in the P6 family and Pentium processors. While the general concept of selecting, filtering, counting, and reading performance events through the WRMSR, RDMSR, and RDPMC instructions is unchanged, the setup mechanism and MSR layouts are incompatible with the P6 family and Pentium processor mechanisms. Also, the RDPMC instruction has been enhanced to read the the additional performance counters provided in the Pentium 4 and Intel Xeon processors and to allow faster reading of counters.

The event monitoring mechanism provided with the Pentium 4 and Intel Xeon processors (based on Intel NetBurst microarchitecture) consists of the following facilities:

- The IA32\_MISC\_ENABLE MSR, which indicates the availability in an Intel 64 or IA-32 processor of the performance monitoring and precise event-based sampling (PEBS) facilities.
- Event selection control (ESCR) MSRs for selecting events to be monitored with specific performance counters. The number available differs by family and model (43 to 45).
- 18 performance counter MSRs for counting events.
- 18 counter configuration control (CCCR) MSRs, with one CCCR associated with each performance counter. CCCRs sets up an associated performance counter for a specific method of counting.
- A debug store (DS) save area in memory for storing PEBS records.
- The IA32\_DS\_AREA MSR, which establishes the location of the DS save area.
- The debug store (DS) feature flag (bit 21) returned by the CPUID instruction, which indicates the availability of the DS mechanism.
- The MSR\_PEBS\_ENABLE MSR, which enables the PEBS facilities and replay tagging used in at-retirement event counting.
- A set of predefined events and event metrics that simplify the setting up of the performance counters to count specific events.

Table 30-28 lists the performance counters and their associated CCCRs, along with the ESCRs that select events to be counted for each performance counter. Predefined event metrics and events are listed in Appendix A, "Performance-Monitoring Events."

PERFORMANCE MONITORING

Table 30-28. Performance Counter MSRs and Associated CCCR and ESCR MSRs (Pentium 4 and Intel Xeon Processors)

### NOTES:

1. MSR\_IO\_ESCRO and MSR\_IO\_ESCR1 are available only on early processor builds (family 0FH, models 01H-02H). These MSRs are not available on later versions.

The types of events that can be counted with these performance monitoring facilities are divided into two classes: non-retirement events and at-retirement events.

- Non-retirement events (see Table A-13) are events that occur any time during instruction execution (such as bus transactions or cache transactions).
- At-retirement events (see Table A-14) are events that are counted at the retirement stage of instruction execution, which allows finer granularity in counting events and capturing machine state.

The at-retirement counting mechanism includes facilities for tagging μops that have encountered a particular performance event during instruction execution. Tagging allows events to be sorted between those that occurred on an execution path that resulted in architectural state being committed at retirement as well as events that occurred on an execution path where the results were eventually cancelled and never committed to architectural state (such as, the execution of a mispredicted branch).

The Pentium 4 and Intel Xeon processor performance monitoring facilities support the three usage models described below. The first two models can be used to count both non-retirement and at-retirement events; the third model is used to count a subset of at-retirement events:

- **Event counting** — A performance counter is configured to count one or more types of events. While the counter is counting, software reads the counter at selected intervals to determine the number of events that have been counted between the intervals.
- **Non-precise event-based sampling** — A performance counter is configured to count one or more types of events and to generate an interrupt when it

overflows. To trigger an overflow, the counter is preset to a modulus value that will cause the counter to overflow after a specific number of events have been counted.

When the counter overflows, the processor generates a performance monitoring interrupt (PMI). The interrupt service routine for the PMI then records the return instruction pointer (RIP), resets the modulus, and restarts the counter. Code performance can be analyzed by examining the distribution of RIPs with a tool like the VTune™ Performance Analyzer.

- **Precise event-based sampling (PEBS) —** This type of performance monitoring is similar to non-precise event-based sampling, except that a memory buffer is used to save a record of the architectural state of the processor whenever the counter overflows. The records of architectural state provide additional information for use in performance tuning. Precise event-based sampling can be used to count only a subset of at-retirement events.

The following sections describe the MSRs and data structures used for performance monitoring in the Pentium 4 and Intel Xeon processors.

### 30.9.1 ESCR MSRs

The 45 ESCR MSRs (see Table 30-28) allow software to select specific events to be countered. Each ESCR is usually associated with a pair of performance counters (see Table 30-28) and each performance counter has several ESCRs associated with it (allowing the events counted to be selected from a variety of events).

Figure 30-33 shows the layout of an ESCR MSR. The functions of the flags and fields are:

- **USR flag, bit 2 —** When set, events are counted when the processor is operating at a current privilege level (CPL) of 1, 2, or 3. These privilege levels are generally used by application code and unprotected operating system code.
- **OS flag, bit 3 —** When set, events are counted when the processor is operating at CPL of 0. This privilege level is generally reserved for protected operating system code. (When both the OS and USR flags are set, events are counted at all privilege levels.)

## PERFORMANCE MONITORING

Figure 30-33. Event Selection Control Register (ESCR) for Pentium 4 and Intel Xeon Processors without Intel HT Technology Support

- **Tag enable, bit 4** — When set, enables tagging of μops to assist in at-retirement event counting; when clear, disables tagging. See Section 30.9.6, “At-Retirement Counting.”
- **Tag value field, bits 5 through 8** — Selects a tag value to associate with a μop to assist in at-retirement event counting.
- **Event mask field, bits 9 through 24** — Selects events to be counted from the event class selected with the event select field.
- **Event select field, bits 25 through 30** — Selects a class of events to be counted. The events within this class that are counted are selected with the event mask field.

When setting up an ESCR, the event select field is used to select a specific class of events to count, such as retired branches. The event mask field is then used to select one or more of the specific events within the class to be counted. For example, when counting retired branches, four different events can be counted: branch not taken predicted, branch not taken mispredicted, branch taken predicted, and branch taken mispredicted. The OS and USR flags allow counts to be enabled for events that occur when operating system code and/or application code are being executed. If neither the OS nor USR flag is set, no events will be counted.

The ESCRs are initialized to all 0s on reset. The flags and fields of an ESCR are configured by writing to the ESCR using the WRMSR instruction. Table 30-28 gives the addresses of the ESCR MSRs.

Writing to an ESCR MSR does not enable counting with its associated performance counter; it only selects the event or events to be counted. The CCCR for the selected performance counter must also be configured. Configuration of the CCCR includes selecting the ESCR and enabling the counter.

### 30.9.2 Performance Counters

The performance counters in conjunction with the counter configuration control registers (CCCRs) are used for filtering and counting the events selected by the ESCRs. The Pentium 4 and Intel Xeon processors provide 18 performance counters organized into 9 pairs. A pair of performance counters is associated with a particular subset of events and ESCR's (see Table 30-28). The counter pairs are partitioned into four groups:

- The BPU group, includes two performance counter pairs:
  - MSR\_BPU\_COUNTER0 and MSR\_BPU\_COUNTER1.
  - MSR\_BPU\_COUNTER2 and MSR\_BPU\_COUNTER3.
- The MS group, includes two performance counter pairs:
  - MSR\_MS\_COUNTER0 and MSR\_MS\_COUNTER1.
  - MSR\_MS\_COUNTER2 and MSR\_MS\_COUNTER3.
- The FLAME group, includes two performance counter pairs:
  - MSR\_FLAME\_COUNTER0 and MSR\_FLAME\_COUNTER1.
  - MSR\_FLAME\_COUNTER2 and MSR\_FLAME\_COUNTER3.
- The IQ group, includes three performance counter pairs:
  - MSR\_IQ\_COUNTER0 and MSR\_IQ\_COUNTER1.
  - MSR\_IQ\_COUNTER2 and MSR\_IQ\_COUNTER3.
  - MSR\_IQ\_COUNTER4 and MSR\_IQ\_COUNTER5.

The MSR\_IQ\_COUNTER4 counter in the IQ group provides support for the PEBS.

Alternate counters in each group can be cascaded: the first counter in one pair can start the first counter in the second pair and vice versa. A similar cascading is possible for the second counters in each pair. For example, within the BPU group of counters, MSR\_BPU\_COUNTER0 can start MSR\_BPU\_COUNTER2 and vice versa, and MSR\_BPU\_COUNTER1 can start MSR\_BPU\_COUNTER3 and vice versa (see Section 30.9.5.6, "Cascading Counters"). The cascade flag in the CCCR register for the performance counter enables the cascading of counters.

Each performance counter is 40-bits wide (see Figure 30-34). The RDPMC instruction has been enhanced in the Pentium 4 and Intel Xeon processors to allow reading of either the full counter-width (40-bits) or the low 32-bits of the counter. Reading the low 32-bits is faster than reading the full counter width and is appropriate in situations where the count is small enough to be contained in 32 bits.

The RDPMC instruction can be used by programs or procedures running at any privilege level and in virtual-8086 mode to read these counters. The PCE flag in control register CR4 (bit 8) allows the use of this instruction to be restricted to only programs and procedures running at privilege level 0.

## PERFORMANCE MONITORING

Figure 30-34. Performance Counter (Pentium 4 and Intel Xeon Processors)

The RDPMC instruction is not serializing or ordered with other instructions. Thus, it does not necessarily wait until all previous instructions have been executed before reading the counter. Similarly, subsequent instructions may begin execution before the RDPMC instruction operation is performed.

Only the operating system, executing at privilege level 0, can directly manipulate the performance counters, using the RDMSR and WRMSR instructions. A secure operating system would clear the PCE flag during system initialization to disable direct user access to the performance-monitoring counters, but provide a user-accessible programming interface that emulates the RDPMC instruction.

Some uses of the performance counters require the counters to be preset before counting begins (that is, before the counter is enabled). This can be accomplished by writing to the counter using the WRMSR instruction. To set a counter to a specified number of counts before overflow, enter a 2s complement negative integer in the counter. The counter will then count from the preset value up to -1 and overflow. Writing to a performance counter in a Pentium 4 or Intel Xeon processor with the WRMSR instruction causes all 40 bits of the counter to be written.

### 30.9.3 CCCR MSRs

Each of the 18 performance counters in a Pentium 4 or Intel Xeon processor has one CCCR MSR associated with it (see Table 30-28). The CCCRs control the filtering and counting of events as well as interrupt generation. Figure 30-35 shows the layout of an CCCR MSR. The functions of the flags and fields are as follows:

- **Enable flag, bit 12** — When set, enables counting; when clear, the counter is disabled. This flag is cleared on reset.
- **ESCR select field, bits 13 through 15** — Identifies the ESCR to be used to select events to be counted with the counter associated with the CCCR.
- **Compare flag, bit 18** — When set, enables filtering of the event count; when clear, disables filtering. The filtering method is selected with the threshold, complement, and edge flags.
- **Complement flag, bit 19** — Selects how the incoming event count is compared with the threshold value. When set, event counts that are less than or equal to the threshold value result in a single count being delivered to the performance

counter; when clear, counts greater than the threshold value result in a count being delivered to the performance counter (see Section 30.9.5.2, "Filtering Events"). The complement flag is not active unless the compare flag is set.

- **Threshold field, bits 20 through 23** — Selects the threshold value to be used for comparisons. The processor examines this field only when the compare flag is set, and uses the complement flag setting to determine the type of threshold comparison to be made. The useful range of values that can be entered in this field depend on the type of event being counted (see Section 30.9.5.2, "Filtering Events").
- **Edge flag, bit 24** — When set, enables rising edge (false-to-true) edge detection of the threshold comparison output for filtering event counts; when clear, rising edge detection is disabled. This flag is active only when the compare flag is set.

Figure 30-35. Counter Configuration Control Register (CCCR)

- **FORCE\_OVF flag, bit 25** — When set, forces a counter overflow on every counter increment; when clear, overflow only occurs when the counter actually overflows.
- **OVF\_PMI flag, bit 26** — When set, causes a performance monitor interrupt (PMI) to be generated when the counter overflows occurs; when clear, disables PMI generation. Note that the PMI is generated on the next event count after the counter has overflowed.

## PERFORMANCE MONITORING

- **Cascade flag, bit 30** — When set, enables counting on one counter of a counter pair when its alternate counter in the other the counter pair in the same counter group overflows (see Section 30.9.2, “Performance Counters,” for further details); when clear, disables cascading of counters.
- **OVF flag, bit 31** — Indicates that the counter has overflowed when set. This flag is a sticky flag that must be explicitly cleared by software.

The CCCRs are initialized to all Os on reset.

The events that an enabled performance counter actually counts are selected and filtered by the following flags and fields in the ESCR and CCCR registers and in the qualification order given:

1. The event select and event mask fields in the ESCR select a class of events to be counted and one or more event types within the class, respectively.
2. The OS and USR flags in the ESCR selected the privilege levels at which events will be counted.
3. The ESCR select field of the CCCR selects the ESCR. Since each counter has several ESCRs associated with it, one ESCR must be chosen to select the classes of events that may be counted.
4. The compare and complement flags and the threshold field of the CCCR select an optional threshold to be used in qualifying an event count.
5. The edge flag in the CCCR allows events to be counted only on rising-edge transitions.

The qualification order in the above list implies that the filtered output of one “stage” forms the input for the next. For instance, events filtered using the privilege level flags can be further qualified by the compare and complement flags and the threshold field, and an event that matched the threshold criteria, can be further qualified by edge detection.

The uses of the flags and fields in the CCCRs are discussed in greater detail in Section 30.9.5, “Programming the Performance Counters for Non-Retirement Events.”

### 30.9.4 Debug Store (DS) Mechanism

The debug store (DS) mechanism was introduced in the Pentium 4 and Intel Xeon processors to allow various types of information to be collected in memory-resident buffers for use in debugging and tuning programs. For the Pentium 4 and Intel Xeon processors, the DS mechanism is used to collect two types of information: branch records and precise event-based sampling (PEBS) records. The availability of the DS mechanism in a processor is indicated with the DS feature flag (bit 21) returned by the CPUID instruction.

See Section 16.4.5, “Branch Trace Store (BTS),” and Section 30.9.7, “Precise Event-Based Sampling (PEBS),” for a description of these facilities. Records collected with the DS mechanism are saved in the DS save area. See Section 16.4.9, “BTS and DS Save Area.”

### 30.9.5 Programming the Performance Counters for Non-Retirement Events

The basic steps to program a performance counter and to count events include the following:

1. Select the event or events to be counted.
2. For each event, select an ESCR that supports the event using the values in the ESCR restrictions row in Table A-13, Appendix A.
3. Match the CCCR Select value and ESCR name in Table A-13 to a value listed in Table 30-28; select a CCCR and performance counter.
4. Set up an ESCR for the specific event or events to be counted and the privilege levels at which the are to be counted.
5. Set up the CCCR for the performance counter by selecting the ESCR and the desired event filters.
6. Set up the CCCR for optional cascading of event counts, so that when the selected counter overflows its alternate counter starts.
7. Set up the CCCR to generate an optional performance monitor interrupt (PMI) when the counter overflows. If PMI generation is enabled, the local APIC must be set up to deliver the interrupt to the processor and a handler for the interrupt must be in place.
8. Enable the counter to begin counting.

#### 30.9.5.1 Selecting Events to Count

Table A-14 in Appendix A lists a set of at-retirement events for the Pentium 4 and Intel Xeon processors. For each event listed in Table A-14, setup information is provided. Table 30-29 gives an example of one of the events.

Table 30-29. Event Example

| Event Name     | Event Parameters         | Parameter Value                        | Description                                                                                                                                        |
|----------------|--------------------------|----------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------|
| branch_retired |                          |                                        | Counts the retirement of a branch. Specify one or more mask bits to select any combination of branch taken, not-taken, predicted and mispredicted. |
|                | ESCR restrictions        | MSR_CRU_ESCR2<br>MSR_CRU_ESCR3         | See Table 15-3 for the addresses of the ESCR MSRs                                                                                                  |
|                | Counter numbers per ESCR | ESCR2: 12, 13, 16<br>ESCR3: 14, 15, 17 | The counter numbers associated with each ESCR are provided. The performance counters and corresponding CCCRs can be obtained from Table 15-3.      |

Table 30-29. Event Example (Contd.)

| Event Name | Event Parameters                     | Parameter Value                              | Description                                                                                                                           |
|------------|--------------------------------------|----------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------|

|            | CCCR Select                          | 05H                                          | CCCR[15:13]                                                                                                                           |
|            | Event Specific Notes                 |                                              | P6: EMON_BR_INST_RETIRE                                                                                                               |
|            | Can Support PEBS                     | No                                           |                                                                                                                                       |
|            | Requires Additional MSRs for Tagging | No                                           |                                                                                                                                       |

For Table A-13 and Table A-14, Appendix A, the name of the event is listed in the Event Name column and parameters that define the event and other information are listed in the Event Parameters column. The Parameter Value and Description columns give specific parameters for the event and additional description information. Entries in the Event Parameters column are described below.

- **ESCR restrictions** — Lists the ESCRs that can be used to program the event. Typically only one ESCR is needed to count an event.
- **Counter numbers per ESCR** — Lists which performance counters are associated with each ESCR. Table 30-28 gives the name of the counter and CCCR for each counter number. Typically only one counter is needed to count the event.
- **ESCR event select** — Gives the value to be placed in the event select field of the ESCR to select the event.
- **ESCR event mask** — Gives the value to be placed in the Event Mask field of the ESCR to select sub-events to be counted. The parameter value column defines the documented bits with relative bit position offset starting from 0, where the absolute bit position of relative offset 0 is bit 9 of the ESCR. All undocumented bits are reserved and should be set to 0.
- **CCCR select** — Gives the value to be placed in the ESCR select field of the CCCR associated with the counter to select the ESCR to be used to define the event. This value is not the address of the ESCR; it is the number of the ESCR from the Number column in Table 30-28.
- **Event specific notes** — Gives additional information about the event, such as the name of the same or a similar event defined for the P6 family processors.
- **Can support PEBS** — Indicates if PEBS is supported for the event (only supplied for at-retirement events listed in Table A-14.)

- **Requires additional MSR for tagging** — Indicates which if any additional MSRs must be programmed to count the events (only supplied for the at-retirement events listed in Table A-14.)

#### NOTE

The performance-monitoring events listed in Appendix A, "Performance-Monitoring Events," are intended to be used as guides for performance tuning. The counter values reported are not guaranteed to be absolutely accurate and should be used as a relative guide for tuning. Known discrepancies are documented where applicable.

The following procedure shows how to set up a performance counter for basic counting; that is, the counter is set up to count a specified event indefinitely, wrapping around whenever it reaches its maximum count. This procedure is continued through the following four sections.

Using information in Table A-13, Appendix A, an event to be counted can be selected as follows:

1. Select the event to be counted.
2. Select the ESCR to be used to select events to be counted from the ESCRs field.
3. Select the number of the counter to be used to count the event from the Counter Numbers Per ESCR field.
4. Determine the name of the counter and the CCCR associated with the counter, and determine the MSR addresses of the counter, CCCR, and ESCR from Table 30-28.
5. Use the WRMSR instruction to write the ESCR Event Select and ESCR Event Mask values into the appropriate fields in the ESCR. At the same time set or clear the USR and OS flags in the ESCR as desired.
6. Use the WRMSR instruction to write the CCCR Select value into the appropriate field in the CCCR.

#### NOTE

Typically all the fields and flags of the CCCR will be written with one WRMSR instruction; however, in this procedure, several WRMSR writes are used to more clearly demonstrate the uses of the various CCCR fields and flags.

This setup procedure is continued in the next section, Section 30.9.5.2, "Filtering Events."

#### 30.9.5.2 Filtering Events

Each counter receives up to 4 input lines from the processor hardware from which it is counting events. The counter treats these inputs as binary inputs (input 0 has a

## PERFORMANCE MONITORING

value of 1, input 1 has a value of 2, input 3 has a value of 4, and input 3 has a value of 8). When a counter is enabled, it adds this binary input value to the counter value on each clock cycle. For each clock cycle, the value added to the counter can then range from 0 (no event) to 15.

For many events, only the 0 input line is active, so the counter is merely counting the clock cycles during which the 0 input is asserted. However, for some events two or more input lines are used. Here, the counters threshold setting can be used to filter events. The compare, complement, threshold, and edge fields control the filtering of counter increments by input value.

If the compare flag is set, then a “greater than” or a “less than or equal to” comparison of the input value vs. a threshold value can be made. The complement flag selects “less than or equal to” (flag set) or “greater than” (flag clear). The threshold field selects a threshold value of from 0 to 15. For example, if the complement flag is cleared and the threshold field is set to 6, than any input value of 7 or greater on the 4 inputs to the counter will cause the counter to be incremented by 1, and any value less than 7 will cause an increment of 0 (or no increment) of the counter. Conversely, if the complement flag is set, any value from 0 to 6 will increment the counter and any value from 7 to 15 will not increment the counter. Note that when a threshold condition has been satisfied, the input to the counter is always 1, not the input value that is presented to the threshold filter.

The edge flag provides further filtering of the counter inputs when a threshold comparison is being made. The edge flag is only active when the compare flag is set. When the edge flag is set, the resulting output from the threshold filter (a value of 0 or 1) is used as an input to the edge filter. Each clock cycle, the edge filter examines the last and current input values and sends a count to the counter only when it detects a “rising edge” event; that is, a false-to-true transition. Figure 30-36 illustrates rising edge filtering.

The following procedure shows how to configure a CCCR to filter events using the threshold filter and the edge filter. This procedure is a continuation of the setup procedure introduced in Section 30.9.5.1, “Selecting Events to Count.”

7. (Optional) To set up the counter for threshold filtering, use the WRMSR instruction to write values in the CCCR compare and complement flags and the threshold field:

- Set the compare flag.
- Set or clear the complement flag for less than or equal to or greater than comparisons, respectively.
- Enter a value from 0 to 15 in the threshold field.

8. (Optional) Select rising edge filtering by setting the CCCR edge flag.

This setup procedure is continued in the next section, Section 30.9.5.3, “Starting Event Counting.”

Figure 30-36. Effects of Edge Filtering

### 30.9.5.3 Starting Event Counting

Event counting by a performance counter can be initiated in either of two ways. The typical way is to set the enable flag in the counter's CCCR. Following the instruction to set the enable flag, event counting begins and continues until it is stopped (see Section 30.9.5.5, "Halting Event Counting").

The following procedural step shows how to start event counting. This step is a continuation of the setup procedure introduced in Section 30.9.5.2, "Filtering Events."

9. To start event counting, use the WRMSR instruction to set the CCCR enable flag for the performance counter.

This setup procedure is continued in the next section, Section 30.9.5.4, "Reading a Performance Counter's Count."

The second way that a counter can be started by using the cascade feature. Here, the overflow of one counter automatically starts its alternate counter (see Section 30.9.5.6, "Cascading Counters").

### 30.9.5.4 Reading a Performance Counter's Count

The Pentium 4 and Intel Xeon processors' performance counters can be read using either the RDPMC or RDMSR instructions. The enhanced functions of the RDPMC instruction (including fast read) are described in Section 30.9.2, "Performance Counters." These instructions can be used to read a performance counter while it is counting or when it is stopped.

The following procedural step shows how to read the event counter. This step is a continuation of the setup procedure introduced in Section 30.9.5.3, "Starting Event Counting."

10. To read a performance counters current event count, execute the RDPMC instruction with the counter number obtained from Table 30-28 used as an operand.

## PERFORMANCE MONITORING

This setup procedure is continued in the next section, Section 30.9.5.5, "Halting Event Counting."

### 30.9.5.5 Halting Event Counting

After a performance counter has been started (enabled), it continues counting indefinitely. If the counter overflows (goes one count past its maximum count), it wraps around and continues counting. When the counter wraps around, it sets its OVF flag to indicate that the counter has overflowed. The OVF flag is a sticky flag that indicates that the counter has overflowed at least once since the OVF bit was last cleared.

To halt counting, the CCCR enable flag for the counter must be cleared.

The following procedural step shows how to stop event counting. This step is a continuation of the setup procedure introduced in Section 30.9.5.4, "Reading a Performance Counter's Count."

11. To stop event counting, execute a WRMSR instruction to clear the CCCR enable flag for the performance counter.

To halt a cascaded counter (a counter that was started when its alternate counter overflowed), either clear the Cascade flag in the cascaded counter's CCCR MSR or clear the OVF flag in the alternate counter's CCCR MSR.

### 30.9.5.6 Cascading Counters

As described in Section 30.9.2, "Performance Counters," eighteen performance counters are implemented in pairs. Nine pairs of counters and associated CCCRs are further organized as four blocks: BPU, MS, FLAME, and IQ (see Table 30-28). The first three blocks contain two pairs each. The IQ block contains three pairs of counters (12 through 17) with associated CCCRs (MSR\_IQ\_CCCR0 through MSR\_IQ\_CCCR5).

The first 8 counter pairs (0 through 15) can be programmed using ESCRs to detect performance monitoring events. Pairs of ESCRs in each of the four blocks allow many different types of events to be counted. The cascade flag in the CCCR MSR allows nested monitoring of events to be performed by cascading one counter to a second counter located in another pair in the same block (see Figure 30-35 for the location of the flag).

Counters 0 and 1 form the first pair in the BPU block. Either counter 0 or 1 can be programmed to detect an event via MSR\_MO\_B\_ESCRO. Counters 0 and 2 can be cascaded in any order, as can counters 1 and 3. It's possible to set up 4 counters in the same block to cascade on two pairs of independent events. The pairing described also applies to subsequent blocks. Since the IQ PUB has two extra counters, cascading operates somewhat differently if 16 and 17 are involved. In the IQ block, counter 16 can only be cascaded from counter 14 (not from 12); counter 14 cannot be cascaded from counter 16 using the CCCR cascade bit mechanism. Similar restrictions apply to counter 17.

### Example 30-1. Counting Events

Assume a scenario where counter X is set up to count 200 occurrences of event A; then counter Y is set up to count 400 occurrences of event B. Each counter is set up to count a specific event and overflow to the next counter. In the above example, counter X is preset for a count of -200 and counter Y for a count of -400; this setup causes the counters to overflow on the 200th and 400th counts respectively.

Continuing this scenario, counter X is set up to count indefinitely and wraparound on overflow. This is described in the basic performance counter setup procedure that begins in Section 30.9.5.1, "Selecting Events to Count." Counter Y is set up with the cascade flag in its associated CCCR MSR set to 1 and its enable flag set to 0.

To begin the nested counting, the enable bit for the counter X is set. Once enabled, counter X counts until it overflows. At this point, counter Y is automatically enabled and begins counting. Thus counter X overflows after 200 occurrences of event A. Counter Y then starts, counting 400 occurrences of event B before overflowing. When performance counters are cascaded, the counter Y would typically be set up to generate an interrupt on overflow. This is described in Section 30.9.5.8, "Generating an Interrupt on Overflow."

The cascading counters mechanism can be used to count a single event. The counting begins on one counter then continues on the second counter after the first counter overflows. This technique doubles the number of event counts that can be recorded, since the contents of the two counters can be added together.

### 30.9.5.7 EXTENDED CASCADING

Extended cascading is a model-specific feature in the Intel NetBurst microarchitecture. The feature is available to Pentium 4 and Xeon processor family with family encoding of 15 and model encoding greater than or equal to 2. This feature uses bit 11 in CCCRs associated with the IQ block. See Table 30-30.

Table 30-30. CCR Names and Bit Positions

| CCCR Name:Bit Position | Bit Name     | Description                               |
|------------------------|--------------|-------------------------------------------|
| MSR_IQ_CCCR1 2:11      | Reserved     |                                           |
| MSR_IQ_CCCR0:11        | CASCNT4INT00 | Allow counter 4 to cascade into counter 0 |
| MSR_IQ_CCCR3:11        | CASCNT5INT03 | Allow counter 5 to cascade into counter 3 |
| MSR_IQ_CCCR4:11        | CASCNT5INT04 | Allow counter 5 to cascade into counter 4 |
| MSR_IQ_CCCR5:11        | CASCNT4INT05 | Allow counter 4 to cascade into counter 5 |

## PERFORMANCE MONITORING

The extended cascading feature can be adapted to the sampling usage model for performance monitoring. However, it is known that performance counters do not generate PMI in cascade mode or extended cascade mode due to an erratum. This erratum applies to Pentium 4 and Intel Xeon processors with model encoding of 2. For Pentium 4 and Intel Xeon processors with model encoding of 0 and 1, the erratum applies to processors with stepping encoding greater than 09H.

Counters 16 and 17 in the IQ block are frequently used in precise event-based sampling or at-retirement counting of events indicating a stalled condition in the pipeline. Neither counter 16 or 17 can initiate the cascading of counter pairs using the cascade bit in a CCCR.

Extended cascading permits performance monitoring tools to use counters 16 and 17 to initiate cascading of two counters in the IQ block. Extended cascading from counter 16 and 17 is conceptually similar to cascading other counters, but instead of using CASCADE bit of a CCCR, one of the four CASCNTxINTOy bits is used.

### Example 30-2. Scenario for Extended Cascading

A usage scenario for extended cascading is to sample instructions retired on logical processor 1 after the first 4096 instructions retired on logical processor 0. A procedure to program extended cascading in this scenario is outlined below:

1. Write the value 0 to counter 12.
2. Write the value 04000603H to MSR\_CRU\_ESCRO (corresponding to selecting the NBOGNTAG and NBOGTAG event masks with qualification restricted to logical processor 1).
3. Write the value 04038800H to MSR\_IQ\_CCCR0. This enables CASCNT4INTO0 and OVF\_PMI. An ISR can sample on instruction addresses in this case (do not set ENABLE, or CASCADE).
4. Write the value FFFF000H into counter 16.1.
5. Write the value 0400060CH to MSR\_CRU\_ESCR2 (corresponding to selecting the NBOGNTAG and NBOGTAG event masks with qualification restricted to logical processor 0).
6. Write the value 00039000H to MSR\_IQ\_CCCR4 (set ENABLE bit, but not OVF\_PMI).

Another use for cascading is to locate stalled execution in a multithreaded application. Assume MOB replays in thread B cause thread A to stall. Getting a sample of the stalled execution in this scenario could be accomplished by:

1. Set up counter B to count MOB replays on thread B.
2. Set up counter A to count resource stalls on thread A; set its force overflow bit and the appropriate CASCNTxINTOy bit.
3. Use the performance monitoring interrupt to capture the program execution data of the stalled thread.

### 30.9.5.8 Generating an Interrupt on Overflow

Any performance counter can be configured to generate a performance monitor interrupt (PMI) if the counter overflows. The PMI interrupt service routine can then collect information about the state of the processor or program when overflow occurred. This information can then be used with a tool like the Intel® VTune™ Performance Analyzer to analyze and tune program performance.

To enable an interrupt on counter overflow, the OVR\_PMI flag in the counter's associated CCCR MSR must be set. When overflow occurs, a PMI is generated through the local APIC. (Here, the performance counter entry in the local vector table [LVT] is set up to deliver the interrupt generated by the PMI to the processor.)

The PMI service routine can use the OVF flag to determine which counter overflowed when multiple counters have been configured to generate PMIs. Also, note that these processors mask PMIs upon receiving an interrupt. Clear this condition before leaving the interrupt handler.

When generating interrupts on overflow, the performance counter being used should be preset to value that will cause an overflow after a specified number of events are counted plus 1. The simplest way to select the preset value is to write a negative number into the counter, as described in Section 30.9.5.6, "Cascading Counters." Here, however, if an interrupt is to be generated after 100 event counts, the counter should be preset to minus 100 plus 1 (-100 + 1), or -99. The counter will then overflow after it counts 99 events and generate an interrupt on the next (100th) event counted. The difference of 1 for this count enables the interrupt to be generated immediately after the selected event count has been reached, instead of waiting for the overflow to be propagation through the counter.

Because of latency in the microarchitecture between the generation of events and the generation of interrupts on overflow, it is sometimes difficult to generate an interrupt close to an event that caused it. In these situations, the FORCE\_OVF flag in the CCCR can be used to improve reporting. Setting this flag causes the counter to overflow on every counter increment, which in turn triggers an interrupt after every counter increment.

### 30.9.5.9 Counter Usage Guideline

There are some instances where the user must take care to configure counting logic properly, so that it is not powered down. To use any ESCR, even when it is being used just for tagging, (any) one of the counters that the particular ESCR (or its paired ESCR) can be connected to should be enabled. If this is not done, 0 counts may result. Likewise, to use any counter, there must be some event selected in a corresponding ESCR (other than no\_event, which generally has a select value of 0).

### 30.9.6 At-Retirement Counting

At-retirement counting provides a means counting only events that represent work committed to architectural state and ignoring work that was performed speculatively and later discarded.

The Intel NetBurst microarchitecture used in the Pentium 4 and Intel Xeon processors performs many speculative activities in an attempt to increase effective processing speeds. One example of this speculative activity is branch prediction. The Pentium 4 and Intel Xeon processors typically predict the direction of branches and then decode and execute instructions down the predicted path in anticipation of the actual branch decision. When a branch misprediction occurs, the results of instructions that were decoded and executed down the mispredicted path are canceled. If a performance counter was set up to count all executed instructions, the count would include instructions whose results were canceled as well as those whose results committed to architectural state.

To provide finer granularity in event counting in these situations, the performance monitoring facilities provided in the Pentium 4 and Intel Xeon processors provide a mechanism for tagging events and then counting only those tagged events that represent committed results. This mechanism is called "at-retirement counting."

Tables A-14 through A-18 list predefined at-retirement events and event metrics that can be used to for tagging events when using at retirement counting. The following terminology is used in describing at-retirement counting:

- **Bogus, non-bogus, retire** — In at-retirement event descriptions, the term "bogus" refers to instructions or  $\mu$ ops that must be canceled because they are on a path taken from a mispredicted branch. The terms "retired" and "non-bogus" refer to instructions or  $\mu$ ops along the path that results in committed architectural state changes as required by the program being executed. Thus instructions and  $\mu$ ops are either bogus or non-bogus, but not both. Several of the Pentium 4 and Intel Xeon processors' performance monitoring events (such as, Instruction\_Retired and Uops\_Retired in Table A-14) can count instructions or  $\mu$ ops that are retired based on the characterization of bogus" versus non-bogus.
- **Tagging** — Tagging is a means of marking  $\mu$ ops that have encountered a particular performance event so they can be counted at retirement. During the course of execution, the same event can happen more than once per  $\mu$ op and a direct count of the event would not provide an indication of how many  $\mu$ ops encountered that event.

The tagging mechanisms allow a  $\mu$ op to be tagged once during its lifetime and thus counted once at retirement. The retired suffix is used for performance metrics that increment a count once per  $\mu$ op, rather than once per event. For example, a  $\mu$ op may encounter a cache miss more than once during its life time, but a "Miss Retired" metric (that counts the number of retired  $\mu$ ops that encountered a cache miss) will increment only once for that  $\mu$ op. A "Miss Retired" metric would be useful for characterizing the performance of the cache hierarchy for a particular instruction sequence. Details of various performance metrics and how these can be constructed using the Pentium 4 and Intel Xeon processors

performance events are provided in the *Intel Pentium 4 Processor Optimization Reference Manual* (see Section 1.4, "Related Literature").

- **Replay** — To maximize performance for the common case, the Intel NetBurst microarchitecture aggressively schedules  $\mu$ ops for execution before all the conditions for correct execution are guaranteed to be satisfied. In the event that all of these conditions are not satisfied,  $\mu$ ops must be reissued. The mechanism that the Pentium 4 and Intel Xeon processors use for this reissuing of  $\mu$ ops is called replay. Some examples of replay causes are cache misses, dependence violations, and unforeseen resource constraints. In normal operation, some number of replays is common and unavoidable. An excessive number of replays is an indication of a performance problem.
- **Assist** — When the hardware needs the assistance of microcode to deal with some event, the machine takes an assist. One example of this is an underflow condition in the input operands of a floating-point operation. The hardware must internally modify the format of the operands in order to perform the computation. Assists clear the entire machine of  $\mu$ ops before they begin and are costly.

### 30.9.6.1 Using At-Retirement Counting

The Pentium 4 and Intel Xeon processors allow counting both events and  $\mu$ ops that encountered a specified event. For a subset of the at-retirement events listed in Table A-14, a  $\mu$ op may be tagged when it encounters that event. The tagging mechanisms can be used in non-precise event-based sampling, and a subset of these mechanisms can be used in PEBS. There are four independent tagging mechanisms, and each mechanism uses a different event to count  $\mu$ ops tagged with that mechanism:

- **Front-end tagging** — This mechanism pertains to the tagging of  $\mu$ ops that encountered front-end events (for example, trace cache and instruction counts) and are counted with the Front\_end\_event event
- **Execution tagging** — This mechanism pertains to the tagging of  $\mu$ ops that encountered execution events (for example, instruction types) and are counted with the Execution\_Event event.
- **Replay tagging** — This mechanism pertains to tagging of  $\mu$ ops whose retirement is replayed (for example, a cache miss) and are counted with the Replay\_event event. Branch mispredictions are also tagged with this mechanism.
- **No tags** — This mechanism does not use tags. It uses the Instr\_retired and the Uops\_retired events.

Each tagging mechanism is independent from all others; that is, a  $\mu$ op that has been tagged using one mechanism will not be detected with another mechanism's tagged- $\mu$ op detector. For example, if  $\mu$ ops are tagged using the front-end tagging mechanisms, the Replay\_event will not count those as tagged  $\mu$ ops unless they are also tagged using the replay tagging mechanism. However, execution tags allow up to four different types of  $\mu$ ops to be counted at retirement through execution tagging.

The independence of tagging mechanisms does not hold when using PEBS. When using PEBS, only one tagging mechanism should be used at a time.

## PERFORMANCE MONITORING

Certain kinds of  $\mu$ ops that cannot be tagged, including I/O, uncacheable and locked accesses, returns, and far transfers.

Table A-14 lists the performance monitoring events that support at-retirement counting: specifically the Front\_end\_event, Execution\_event, Replay\_event, Inst\_retired and Uops\_retired events. The following sections describe the tagging mechanisms for using these events to tag  $\mu$ op and count tagged  $\mu$ ops.

### 30.9.6.2 Tagging Mechanism for Front\_end\_event

The Front\_end\_event counts  $\mu$ ops that have been tagged as encountering any of the following events:

- **$\mu$ op decode events** — Tagging  $\mu$ ops for  $\mu$ op decode events requires specifying bits in the ESCR associated with the performance-monitoring event, Uop\_type.
- **Trace cache events** — Tagging  $\mu$ ops for trace cache events may require specifying certain bits in the MSR\_TC\_PRECISE\_EVENT MSR (see Table A-16).

Table A-14 describes the Front\_end\_event and Table A-16 describes metrics that are used to set up a Front\_end\_event count.

The MSRs specified in the Table A-14 that are supported by the front-end tagging mechanism must be set and one or both of the NBOGUS and BOGUS bits in the Front\_end\_event event mask must be set to count events. None of the events currently supported requires the use of the MSR\_TC\_PRECISE\_EVENT MSR.

### 30.9.6.3 Tagging Mechanism For Execution\_event

Table A-14 describes the Execution\_event and Table A-17 describes metrics that are used to set up an Execution\_event count.

The execution tagging mechanism differs from other tagging mechanisms in how it causes tagging. One *upstream* ESCR is used to specify an event to detect and to specify a tag value (bits 5 through 8) to identify that event. A second *downstream* ESCR is used to detect  $\mu$ ops that have been tagged with that tag value identifier using Execution\_event for the event selection.

The upstream ESCR that counts the event must have its tag enable flag (bit 4) set and must have an appropriate tag value mask entered in its tag value field. The 4-bit tag value mask specifies which of tag bits should be set for a particular  $\mu$ op. The value selected for the tag value should coincide with the event mask selected in the downstream ESCR. For example, if a tag value of 1 is set, then the event mask of NBOGUS0 should be enabled, correspondingly in the downstream ESCR. The downstream ESCR detects and counts tagged  $\mu$ ops. The normal (not tag value) mask bits in the downstream ESCR specify which tag bits to count. If any one of the tag bits selected by the mask is set, the related counter is incremented by one. This mechanism is summarized in the Table A-17 metrics that are supported by the execution tagging mechanism. The tag enable and tag value bits are irrelevant for the downstream ESCR used to select the Execution\_event.

The four separate tag bits allow the user to simultaneously but distinctly count up to four execution events at retirement. (This applies for non-precise event-based sampling. There are additional restrictions for PEBS as noted in Section 30.9.7.3, "Setting Up the PEBS Buffer.") It is also possible to detect or count combinations of events by setting multiple tag value bits in the upstream ESCR or multiple mask bits in the downstream ESCR. For example, use a tag value of 3H in the upstream ESCR and use NBOGUS0/NBOGUS1 in the downstream ESCR event mask.

#### 30.9.6.4 Tagging Mechanism for Replay\_event

Table A-14 describes the Replay\_event and Table A-18 describes metrics that are used to set up an Replay\_event count.

The replay mechanism enables tagging of  $\mu$ ops for a subset of all replays before retirement. Use of the replay mechanism requires selecting the type of  $\mu$ op that may experience the replay in the MSR\_PEBS\_MATRIX\_VERT MSR and selecting the type of event in the MSR\_PEBS\_ENABLE MSR. Replay tagging must also be enabled with the UOP\_Tag flag (bit 24) in the MSR\_PEBS\_ENABLE MSR.

The Table A-18 lists the metrics that are support the replay tagging mechanism and the at-retirement events that use the replay tagging mechanism, and specifies how the appropriate MSRs need to be configured. The replay tags defined in Table A-5 also enable Precise Event-Based Sampling (PEBS, see Section 15.9.8). Each of these replay tags can also be used in normal sampling by not setting Bit 24 nor Bit 25 in IA\_32\_PEBS\_ENABLE\_MSR. Each of these metrics requires that the Replay\_Event (see Table A-14) be used to count the tagged  $\mu$ ops.

### 30.9.7 Precise Event-Based Sampling (PEBS)

The debug store (DS) mechanism in processors based on Intel NetBurst microarchitecture allow two types of information to be collected for use in debugging and tuning programs: PEBS records and BTS records. See Section 16.4.5, "Branch Trace Store (BTS)," for a description of the BTS mechanism.

PEBS permits the saving of precise architectural information associated with one or more performance events in the precise event records buffer, which is part of the DS save area (see Section 16.4.9, "BTS and DS Save Area"). To use this mechanism, a counter is configured to overflow after it has counted a preset number of events. After the counter overflows, the processor copies the current state of the general-purpose and EFLAGS registers and instruction pointer into a record in the precise event records buffer. The processor then resets the count in the performance counter and restarts the counter. When the precise event records buffer is nearly full, an interrupt is generated, allowing the precise event records to be saved. A circular buffer is not supported for precise event records.

PEBS is supported only for a subset of the at-retirement events: Execution\_event, Front\_end\_event, and Replay\_event. Also, PEBS can only be carried out using the one performance counter, the MSR\_IQ\_COUNTER4 MSR.

## PERFORMANCE MONITORING

In processors based on Intel Core microarchitecture, a similar PEBS mechanism is also supported using IA32\_PMC0 and IA32\_PERFEVTSEL0 MSRs (See Section 30.4.4).

### 30.9.7.1 Detection of the Availability of the PEBS Facilities

The DS feature flag (bit 21) returned by the CPUID instruction indicates (when set) the availability of the DS mechanism in the processor, which supports the PEBS (and BTS) facilities. When this bit is set, the following PEBS facilities are available:

- The PEBS\_UNAVAILABLE flag in the IA32\_MISC\_ENABLE MSR indicates (when clear) the availability of the PEBS facilities, including the MSR\_PEBS\_ENABLE MSR.
- The enable PEBS flag (bit 24) in the MSR\_PEBS\_ENABLE MSR allows PEBS to be enabled (set) or disabled (clear).
- The IA32\_DS\_AREA MSR can be programmed to point to the DS save area.

### 30.9.7.2 Setting Up the DS Save Area

Section 16.4.9.2, "Setting Up the DS Save Area," describes how to set up and enable the DS save area. This procedure is common for PEBS and BTS.

### 30.9.7.3 Setting Up the PEBS Buffer

Only the MSR\_IO\_COUNTER4 performance counter can be used for PEBS. Use the following procedure to set up the processor and this counter for PEBS:

1. Set up the precise event buffering facilities. Place values in the precise event buffer base, precise event index, precise event absolute maximum, and precise event interrupt threshold, and precise event counter reset fields of the DS buffer management area (see Figure 16-5) to set up the precise event records buffer in memory.
2. Enable PEBS. Set the Enable PEBS flag (bit 24) in MSR\_PEBS\_ENABLE MSR.
3. Set up the MSR\_IO\_COUNTER4 performance counter and its associated CCCR and one or more ESCRs for PEBS as described in Tables A-14 through A-18.

### 30.9.7.4 Writing a PEBS Interrupt Service Routine

The PEBS facilities share the same interrupt vector and interrupt service routine (called the DS ISR) with the non-precise event-based sampling and BTS facilities. To handle PEBS interrupts, PEBS handler code must be included in the DS ISR. See Section 16.4.9.5, "Writing the DS Interrupt Service Routine," for guidelines for writing the DS ISR.

### 30.9.7.5 Other DS Mechanism Implications

The DS mechanism is not available in the SMM. It is disabled on transition to the SMM mode. Similarly the DS mechanism is disabled on the generation of a machine check exception and is cleared on processor RESET and INIT.

The DS mechanism is available in real address mode.

### 30.9.8 Operating System Implications

The DS mechanism can be used by the operating system as a debugging extension to facilitate failure analysis. When using this facility, a 25 to 30 times slowdown can be expected due to the effects of the trace store occurring on every taken branch.

Depending upon intended usage, the instruction pointers that are part of the branch records or the PEBS records need to have an association with the corresponding process. One solution requires the ability for the DS specific operating system module to be chained to the context switch. A separate buffer can then be maintained for each process of interest and the MSR pointing to the configuration area saved and setup appropriately on each context switch.

If the BTS facility has been enabled, then it must be disabled and state stored on transition of the system to a sleep state in which processor context is lost. The state must be restored on return from the sleep state.

It is required that an interrupt gate be used for the DS interrupt as opposed to a trap gate to prevent the generation of an endless interrupt loop.

Pages that contain buffers must have mappings to the same physical address for all processes/logical processors, such that any change to CR3 will not change DS addresses. If this requirement cannot be satisfied (that is, the feature is enabled on a per thread/process basis), then the operating system must ensure that the feature is enabled/disabled appropriately in the context switch code.

## 30.10 PERFORMANCE MONITORING AND INTEL HYPER-THREADING TECHNOLOGY IN PROCESSORS BASED ON INTEL NETBURST® MICROARCHITECTURE

The performance monitoring capability of processors based on Intel NetBurst microarchitecture and supporting Intel Hyper-Threading Technology is similar to that described in Section 30.9. However, the capability is extended so that:

- Performance counters can be programmed to select events qualified by logical processor IDs.
- Performance monitoring interrupts can be directed to a specific logical processor within the physical processor.

## PERFORMANCE MONITORING

The sections below describe performance counters, event qualification by logical processor ID, and special purpose bits in ESCRs/CCCRs. They also describe MSR\_PEBS\_ENABLE, MSR\_PEBS\_MATRIX\_VERT, and MSR\_TC\_PRECISE\_EVENT.

### 30.10.1 ESCR MSRs

Figure 30-37 shows the layout of an ESCR MSR in processors supporting Intel Hyper-Threading Technology.

The functions of the flags and fields are as follows:

- **T1\_USR flag, bit 0** — When set, events are counted when thread 1 (logical processor 1) is executing at a current privilege level (CPL) of 1, 2, or 3. These privilege levels are generally used by application code and unprotected operating system code.

Figure 30-37. Event Selection Control Register (ESCR) for the Pentium 4 Processor, Intel Xeon Processor and Intel Xeon Processor MP Supporting Hyper-Threading Technology

- **T1\_OS flag, bit 1** — When set, events are counted when thread 1 (logical processor 1) is executing at CPL of 0. This privilege level is generally reserved for protected operating system code. (When both the T1\_OS and T1\_USR flags are set, thread 1 events are counted at all privilege levels.)
- **T0\_USR flag, bit 2** — When set, events are counted when thread 0 (logical processor 0) is executing at a CPL of 1, 2, or 3.
- **T0\_OS flag, bit 3** — When set, events are counted when thread 0 (logical processor 0) is executing at CPL of 0. (When both the T0\_OS and T0\_USR flags are set, thread 0 events are counted at all privilege levels.)

- **Tag enable, bit 4** — When set, enables tagging of  $\mu$ ops to assist in at-retirement event counting; when clear, disables tagging. See Section 30.9.6, “At-Retirement Counting.”
- **Tag value field, bits 5 through 8** — Selects a tag value to associate with a  $\mu$ op to assist in at-retirement event counting.
- **Event mask field, bits 9 through 24** — Selects events to be counted from the event class selected with the event select field.
- **Event select field, bits 25 through 30** — Selects a class of events to be counted. The events within this class that are counted are selected with the event mask field.

The T0\_OS and T0\_USR flags and the T1\_OS and T1\_USR flags allow event counting and sampling to be specified for a specific logical processor (0 or 1) within an Intel Xeon processor MP (See also: Section 8.4.5, “Identifying Logical Processors in an MP System,” in the *Intel® 64 and IA-32 Architectures Software Developer’s Manual, Volume 3A*).

Not all performance monitoring events can be detected within an Intel Xeon processor MP on a per logical processor basis (see Section 30.10.4, “Performance Monitoring Events”). Some sub-events (specified by an event mask bits) are counted or sampled without regard to which logical processor is associated with the detected event.

### 30.10.2 CCCR MSRs

Figure 30-38 shows the layout of a CCCR MSR in processors supporting Intel Hyper-Threading Technology. The functions of the flags and fields are as follows:

- **Enable flag, bit 12** — When set, enables counting; when clear, the counter is disabled. This flag is cleared on reset
- **ESCR select field, bits 13 through 15** — Identifies the ESCR to be used to select events to be counted with the counter associated with the CCCR.
- **Active thread field, bits 16 and 17** — Enables counting depending on which logical processors are active (executing a thread). This field enables filtering of events based on the state (active or inactive) of the logical processors. The encodings of this field are as follows:
  - 00** — None. Count only when neither logical processor is active.
  - 01** — Single. Count only when one logical processor is active (either 0 or 1).
  - 10** — Both. Count only when both logical processors are active.
  - 11** — Any. Count when either logical processor is active.

A halted logical processor or a logical processor in the “wait for SIPI” state is considered inactive.

## PERFORMANCE MONITORING

- **Compare flag, bit 18** — When set, enables filtering of the event count; when clear, disables filtering. The filtering method is selected with the threshold, complement, and edge flags.

Figure 30-38. Counter Configuration Control Register (CCCR)

- **Complement flag, bit 19** — Selects how the incoming event count is compared with the threshold value. When set, event counts that are less than or equal to the threshold value result in a single count being delivered to the performance counter; when clear, counts greater than the threshold value result in a count being delivered to the performance counter (see Section 30.9.5.2, "Filtering Events"). The compare flag is not active unless the complement flag is set.
- **Threshold field, bits 20 through 23** — Selects the threshold value to be used for comparisons. The processor examines this field only when the compare flag is set, and uses the complement flag setting to determine the type of threshold comparison to be made. The useful range of values that can be entered in this field depend on the type of event being counted (see Section 30.9.5.2, "Filtering Events").
- **Edge flag, bit 24** — When set, enables rising edge (false-to-true) edge detection of the threshold comparison output for filtering event counts; when clear, rising edge detection is disabled. This flag is active only when the compare flag is set.

- **FORCE\_OVF flag, bit 25** — When set, forces a counter overflow on every counter increment; when clear, overflow only occurs when the counter actually overflows.
- **OVF\_PMI\_T0 flag, bit 26** — When set, causes a performance monitor interrupt (PMI) to be sent to logical processor 0 when the counter overflows occurs; when clear, disables PMI generation for logical processor 0. Note that the PMI is generate on the next event count after the counter has overflowed.
- **OVF\_PMI\_T1 flag, bit 27** — When set, causes a performance monitor interrupt (PMI) to be sent to logical processor 1 when the counter overflows occurs; when clear, disables PMI generation for logical processor 1. Note that the PMI is generate on the next event count after the counter has overflowed.
- **Cascade flag, bit 30** — When set, enables counting on one counter of a counter pair when its alternate counter in the other the counter pair in the same counter group overflows (see Section 30.9.2, “Performance Counters,” for further details); when clear, disables cascading of counters.
- **OVF flag, bit 31** — Indicates that the counter has overflowed when set. This flag is a sticky flag that must be explicitly cleared by software.

### 30.10.3 IA32\_PEBS\_ENABLE MSR

In a processor supporting Intel Hyper-Threading Technology and based on the Intel NetBurst microarchitecture, PEBS is enabled and qualified with two bits in the MSR\_PEBS\_ENABLE MSR: bit 25 (ENABLE\_PEBS\_MY\_THR) and 26 (ENABLE\_PEBS\_OTH\_THR) respectively. These bits do not explicitly identify a specific logical processor by logic processor ID(T0 or T1); instead, they allow a software agent to enable PEBS for subsequent threads of execution on the same logical processor on which the agent is running (“my thread”) or for the other logical processor in the physical package on which the agent is not running (“other thread”).

PEBS is supported for only a subset of the at-retirement events: Execution\_event, Front\_end\_event, and Replay\_event. Also, PEBS can be carried out only with two performance counters: MSR\_IQ\_CCCR4 (MSR address 370H) for logical processor 0 and MSR\_IQ\_CCCR5 (MSR address 371H) for logical processor 1.

Performance monitoring tools should use a processor affinity mask to bind the kernel mode components that need to modify the ENABLE\_PEBS\_MY\_THR and ENABLE\_PEBS\_OTH\_THR bits in the MSR\_PEBS\_ENABLE MSR to a specific logical processor. This is to prevent these kernel mode components from migrating between different logical processors due to OS scheduling.

### 30.10.4 Performance Monitoring Events

All of the events listed in Table A-13 and A-14 are available in an Intel Xeon processor MP. When Intel Hyper-Threading Technology is active, many performance monitoring events can be can be qualified by the logical processor ID, which corresponds to bit 0

## PERFORMANCE MONITORING

of the initial APIC ID. This allows for counting an event in any or all of the logical processors. However, not all the events have this logic processor specificity, or thread specificity.

Here, each event falls into one of two categories:

- **Thread specific (TS)** — The event can be qualified as occurring on a specific logical processor.
- **Thread independent (TI)** — The event cannot be qualified as being associated with a specific logical processor.

Table A-19 gives logical processor specific information (TS or TI) for each of the events described in Tables A-13 and A-14. If for example, a TS event occurred in logical processor T0, the counting of the event (as shown in Table 30-31) depends only on the setting of the T0\_USR and T0\_OS flags in the ESCR being used to set up the event counter. The T1\_USR and T1\_OS flags have no effect on the count.

**Table 30-31. Effect of Logical Processor and CPL Qualification for Logical-Processor-Specific (TS) Events**

|                   | T1_OS/T1_USR = 00            | T1_OS/T1_USR = 01                                           | T1_OS/T1_USR = 11                                           | T1_OS/T1_USR = 10                                          |
|-------------------|------------------------------|-------------------------------------------------------------|-------------------------------------------------------------|------------------------------------------------------------|
| T0_OS/T0_USR = 00 | Zero count                   | Counts while T1 in USR                                      | Counts while T1 in OS or USR                                | Counts while T1 in OS                                      |
| T0_OS/T0_USR = 01 | Counts while T0 in USR       | Counts while T0 in USR or T1 in USR                         | Counts while (a) T0 in USR or (b) T1 in OS or (c) T1 in USR | Counts while (a) T0 in OS or (b) T1 in OS                  |
| T0_OS/T0_USR = 11 | Counts while T0 in OS or USR | Counts while (a) T0 in OS or (b) T0 in USR or (c) T1 in USR | Counts irrespective of CPL, T0, T1                          | Counts while (a) T0 in OS or (b) T0 in USR or (c) T1 in OS |
| T0_OS/T0_USR = 10 | Counts T0 in OS              | Counts T0 in OS or T1 in USR                                | Counts while (a) T0 in OS or (b) T1 in OS or (c) T1 in USR  | Counts while (a) T0 in OS or (b) T1 in OS                  |

When a bit in the event mask field is TI, the effect of specifying bit-0-3 of the associated ESCR are described in Table 15-6. For events that are marked as TI in Appendix A, the effect of selectively specifying T0\_USR, T0\_OS, T1\_USR, T1\_OS bits is shown in Table 30-32.

**Table 30-32. Effect of Logical Processor and CPL Qualification for Non-logical-Processor-specific (TI) Events**

|                   | T1_OS/T1_USR = 00                           | T1_OS/T1_USR = 01                           | T1_OS/T1_USR = 11                  | T1_OS/T1_USR = 10                         |
|-------------------|---------------------------------------------|---------------------------------------------|------------------------------------|-------------------------------------------|
| T0_OS/T0_USR = 00 | Zero count                                  | Counts while (a) T0 in USR or (b) T1 in USR | Counts irrespective of CPL, T0, T1 | Counts while (a) T0 in OS or (b) T1 in OS |
| T0_OS/T0_USR = 01 | Counts while (a) T0 in USR or (b) T1 in USR | Counts while (a) T0 in USR or (b) T1 in USR | Counts irrespective of CPL, T0, T1 | Counts irrespective of CPL, T0, T1        |
| T0_OS/T0_USR = 11 | Counts irrespective of CPL, T0, T1          | Counts irrespective of CPL, T0, T1          | Counts irrespective of CPL, T0, T1 | Counts irrespective of CPL, T0, T1        |
| T0_OS/T0_USR = 0  | Counts while (a) T0 in OS or (b) T1 in OS   | Counts irrespective of CPL, T0, T1          | Counts irrespective of CPL, T0, T1 | Counts while (a) T0 in OS or (b) T1 in OS |

## 30.11 COUNTING CLOCKS

The count of cycles, also known as clockticks, forms the basis for measuring how long a program takes to execute. Clockticks are also used as part of efficiency ratios like cycles per instruction (CPI). Processor clocks may stop ticking under circumstances like the following:

- The processor is halted when there is nothing for the CPU to do. For example, the processor may halt to save power while the computer is servicing an I/O request. When Intel Hyper-Threading Technology is enabled, both logical processors must be halted for performance-monitoring counters to be powered down.
- The processor is asleep as a result of being halted or because of a power-management scheme. There are different levels of sleep. In the some deep sleep levels, the time-stamp counter stops counting.

In addition, processor core clocks may undergo transitions at different ratios relative to the processor's bus clock frequency. Some of the situations that can cause processor core clock to undergo frequency transitions include:

- TM2 transitions
- Enhanced Intel SpeedStep Technology transitions (P-state transitions)

For Intel processors that support Intel Dynamic Acceleration or XE operation, the processor core clocks may operate at a frequency that differs from the maximum qualified frequency (as indicated by brand string information reported by CPUID instruction). See Section 30.11.5 for more detail.

## PERFORMANCE MONITORING

There are several ways to count processor clock cycles to monitor performance. These are:

- **Non-halted clockticks** — Measures clock cycles in which the specified logical processor is not halted and is not in any power-saving state. When Intel Hyper-Threading Technology is enabled, ticks can be measured on a per-logical-processor basis. There are also performance events on dual-core processors that measure clockticks per logical processor when the processor is not halted.
- **Non-sleep clockticks** — Measures clock cycles in which the specified physical processor is not in a sleep mode or in a power-saving state. These ticks **cannot** be measured on a logical-processor basis.
- **Time-stamp counter** — Measures clock cycles in which the physical processor is not in deep sleep. These ticks cannot be measured on a logical-processor basis.
- **Reference clockticks** — TM2 or Enhanced Intel SpeedStep technology are two examples of processor features that can cause processor core clockticks to represent non-uniform tick intervals due to change of bus ratios. Performance events that counts clockticks of a constant reference frequency was introduced Intel Core Duo and Intel Core Solo processors. The mechanism is further enhanced on processors based on Intel Core microarchitecture.

Some processor models permit clock cycles to be measured when the physical processor is not in deep sleep (by using the time-stamp counter and the RDTSC instruction). Note that such ticks cannot be measured on a per-logical-processor basis. See Section 16.12, "Time-Stamp Counter," for detail on processor capabilities.

The first two methods use performance counters and can be set up to cause an interrupt upon overflow (for sampling). They may also be useful where it is easier for a tool to read a performance counter than to use a time stamp counter (the timestamp counter is accessed using the RDTSC instruction).

For applications with a significant amount of I/O, there are two ratios of interest:

- **Non-halted CPI** — Non-halted clockticks/instructions retired measures the CPI for phases where the CPU was being used. This ratio can be measured on a logical-processor basis when Intel Hyper-Threading Technology is enabled.
- **Nominal CPI** — Time-stamp counter ticks/instructions retired measures the CPI over the duration of a program, including those periods when the machine halts while waiting for I/O.

### 30.11.1 Non-Halted Clockticks

Use the following procedure to program ESCRs and CCCRs to obtain non-halted clockticks on processors based on Intel NetBurst microarchitecture:

1. Select an ESCR for the global\_power\_events and specify the RUNNING sub-event mask and the desired T0\_OS/T0\_USR/T1\_OS/T1\_USR bits for the targeted processor.

2. Select an appropriate counter.
3. Enable counting in the CCCR for that counter by setting the enable bit.

### 30.11.2 Non-Sleep Clockticks

Performance monitoring counters can be configured to count clockticks whenever the performance monitoring hardware is not powered-down. To count Non-sleep Clockticks with a performance-monitoring counter, do the following:

1. Select one of the 18 counters.
2. Select any of the ESCRs whose events the selected counter can count. Set its event select to anything other than no\_event. This may not seem necessary, but the counter may be disabled if this is not done.
3. Turn threshold comparison on in the CCCR by setting the compare bit to 1.
4. Set the threshold to 15 and the complement to 1 in the CCCR. Since no event can exceed this threshold, the threshold condition is met every cycle and the counter counts every cycle. Note that this overrides any qualification (e.g. by CPL) specified in the ESCR.
5. Enable counting in the CCCR for the counter by setting the enable bit.

In most cases, the counts produced by the non-halted and non-sleep metrics are equivalent if the physical package supports one logical processor and is not placed in a power-saving state. Operating systems may execute an HLT instruction and place a physical processor in a power-saving state.

On processors that support Intel Hyper-Threading Technology (Intel HT Technology), each physical package can support two or more logical processors. Current implementation of Intel HT Technology provides two logical processors for each physical processor. While both logical processors can execute two threads simultaneously, one logical processor may halt to allow the other logical processor to execute without sharing execution resources between two logical processors.

Non-halted Clockticks can be set up to count the number of processor clock cycles for each logical processor whenever the logical processor is not halted (the count may include some portion of the clock cycles for that logical processor to complete a transition to a halted state). Physical processors that support Intel HT Technology enter into a power-saving state if all logical processors halt.

The Non-sleep Clockticks mechanism uses a filtering mechanism in CCCRs. The mechanism will continue to increment as long as one logical processor is not halted or in a power-saving state. Applications may cause a processor to enter into a power-saving state by using an OS service that transfers control to an OS's idle loop. The idle loop then may place the processor into a power-saving state after an implementation-dependent period if there is no work for the processor.

### 30.11.3 Incrementing the Time-Stamp Counter

The time-stamp counter increments when the clock signal on the system bus is active and when the sleep pin is not asserted. The counter value can be read with the RDTSC instruction.

The time-stamp counter and the non-sleep clockticks count may not agree in all cases and for all processors. See Section 16.12, “Time-Stamp Counter,” for more information on counter operation.

### 30.11.4 Non-Halted Reference Clockticks

Software can use either processor-specific performance monitor events (for example: CPU\_CLK\_UNHALTED.BUS on processors based on the Intel Core microarchitecture, and equivalent event specifications on the Intel Core Duo and Intel Core Solo processors) to count non-halted reference clockticks.

These events count reference clock cycles whenever the specified processor is not halted. The counter counts reference cycles associated with a fixed-frequency clock source irrespective of P-state, TM2, or frequency transitions that may occur to the processor.

### 30.11.5 Cycle Counting and Opportunistic Processor Operation

As a result of the state transitions due to opportunistic processor performance operation (see Chapter 14, “Power and Thermal Management”), a logical processor or a processor core can operate at frequency different from that indicated by the processor’s maximum qualified frequency.

The following items are expected to hold true irrespective of when opportunistic processor operation causes state transitions:

- The time stamp counter operates at a fixed-rate frequency of the processor.
- The IA32\_MP自称 counter increments at the same TSC frequency irrespective of any transitions caused by opportunistic processor operation.
- The IA32\_FIXED\_CTR2 counter increments at the same TSC frequency irrespective of any transitions caused by opportunistic processor operation.
- The Local APIC timer operation is unaffected by opportunistic processor operation.
- The TSC, IA32\_MP自称, and IA32\_FIXED\_CTR2 operate at the same, maximum-resolved frequency of the platform, which is equal to the product of scalable bus frequency and maximum resolved bus ratio.

For processors based on Intel Core microarchitecture, the scalable bus frequency is encoded in the bit field MSR\_FSB\_FREQ[2:0] at (0CDH), see Appendix B, “Model-

Specific Registers (MSRs)". The maximum resolved bus ratio can be read from the following bit field:

- If XE operation is disabled, the maximum resolved bus ratio can be read in MSR\_PLATFORM\_ID[12:8]. It corresponds to the maximum qualified frequency.
- If XE operation is enabled, the maximum resolved bus ratio is given in MSR\_PERF\_STAT[44:40], it corresponds to the maximum XE operation frequency configured by BIOS.

XE operation of an Intel 64 processor is implementation specific. XE operation can be enabled only by BIOS. If MSR\_PERF\_STAT[31] is set, XE operation is enabled. The MSR\_PERF\_STAT[31] field is read-only.

## 30.12 PERFORMANCE MONITORING, BRANCH PROFILING AND SYSTEM EVENTS

When performance monitoring facilities and/or branch profiling facilities (see Section 16.5, "Last Branch, Interrupt, and Exception Recording (Intel® Core™ 2 Duo and Intel® Atom™ Processor Family)") are enabled, these facilities capture event counts, branch records and branch trace messages occurring in a logical processor. The occurrence of interrupts, instruction streams due to various interrupt handlers all contribute to the results recorded by these facilities.

If CPUID.01H:ECX.PDCM[bit 15] is 1, the processor supports the IA32\_PERF\_CAPABILITIES MSR. If

IA32\_PERF\_CAPABILITIES.FREEZE\_WHILE\_SMM[Bit 12] is 1, the processor supports the ability for system software using performance monitoring and/or branch profiling facilities to filter out the effects of servicing system management interrupts.

If the FREEZE\_WHILE\_SMM capability is enabled on a logical processor and after an SMI is delivered, the processor will clear all the enable bits of IA32\_PERF\_GLOBAL\_CTRL, save a copy of the content of IA32\_DEBUGCTL and disable LBR, BTF, TR, and BTS fields of IA32\_DEBUGCTL before transferring control to the SMI handler.

The enable bits of IA32\_PERF\_GLOBAL\_CTRL will be set to 1, the saved copy of IA32\_DEBUGCTL prior to SMI delivery will be restored, after the SMI handler issues RSM to complete its servicing.

It is the responsibility of the SMM code to ensure the state of the performance monitoring and branch profiling facilities are preserved upon entry or until prior to exiting the SMM. If any of this state is modified due to actions by the SMM code, the SMM code is required to restore such state to the values present at entry to the SMM handler.

System software is allowed to set IA32\_DEBUGCTL.FREEZE\_WHILE\_SMM\_EN[bit 14] to 1 only supported as indicated by IA32\_PERF\_CAPABILITIES.FREEZE\_WHILE\_SMM[Bit 12] reporting 1.

## PERFORMANCE MONITORING

Figure 30-39. Layout of IA32\_PERF\_CAPABILITIES MSR

## 30.13 PERFORMANCE MONITORING AND DUAL-CORE TECHNOLOGY

The performance monitoring capability of dual-core processors duplicates the microarchitectural resources of a single-core processor implementation. Each processor core has dedicated performance monitoring resources.

In the case of Pentium D processor, each logical processor is associated with dedicated resources for performance monitoring. In the case of Pentium processor Extreme edition, each processor core has dedicated resources, but two logical processors in the same core share performance monitoring resources (see Section 30.10, "Performance Monitoring and Intel Hyper-Threading Technology in Processors Based on Intel NetBurst® Microarchitecture").

## 30.14 PERFORMANCE MONITORING ON 64-BIT INTEL XEON PROCESSOR MP WITH UP TO 8-MBYTE L3 CACHE

The 64-bit Intel Xeon processor MP with up to 8-MByte L3 cache has a CPUID signature of family [0FH], model [03H or 04H]. Performance monitoring capabilities available to Pentium 4 and Intel Xeon processors with the same values (see Section 30.1 and Section 30.10) apply to the 64-bit Intel Xeon processor MP with an L3 cache.

The level 3 cache is connected between the system bus and IOQ through additional control logic. See Figure 30-40.

Figure 30-40. Block Diagram of 64-bit Intel Xeon Processor MP with 8-MByte L3

Additional performance monitoring capabilities and facilities unique to 64-bit Intel Xeon processor MP with an L3 cache are described in this section. The facility for monitoring events consists of a set of dedicated model-specific registers (MSRs), each dedicated to a specific event. Programming of these MSRs requires using RDMSR/WRMSR instructions with 64-bit values.

The lower 32-bits of the MSRs at addresses 107CC through 107D3 are treated as 32 bit performance counter registers. These performance counters can be accessed using RDPMC instruction with the index starting from 18 through 25. The EDX register returns zero when reading these 8 PMCs.

The performance monitoring capabilities consist of four events. These are:

- **IBUSQ event** — This event detects the occurrence of micro-architectural conditions related to the iBUSQ unit. It provides two MSRs: MSR\_IFSB\_IBUSQ0 and MSR\_IFSB\_IBUSQ1. Configure sub-event qualification and enable/disable functions using the high 32 bits of these MSRs. The low 32 bits act as a 32-bit event counter. Counting starts after software writes a non-zero value to one or more of the upper 32 bits. See Figure 30-41.

## PERFORMANCE MONITORING

Figure 30-41. MSR\_IFSB\_IBUSQx, Addresses: 107CCH and 107CDH

- **ISNPQ event** — This event detects the occurrence of microarchitectural conditions related to the ISNPQ unit. It provides two MSRs: MSR\_IFSB\_ISNPQ0 and MSR\_IFSB\_ISNPQ1. Configure sub-event qualifications and enable/disable functions using the high 32 bits of the MSRs. The low 32-bits act as a 32-bit event counter. Counting starts after software writes a non-zero value to one or more of the upper 32-bits. See Figure 30-42.

Figure 30-42. MSR\_IFSB\_ISNPQx, Addresses: 107CEH and 107CFH

- **EFSB event** — This event can detect the occurrence of micro-architectural conditions related to the iFSB unit or system bus. It provides two MSRs: MSR\_EFSB\_DRDY0 and MSR\_EFSB\_DRDY1. Configure sub-event qualifications and enable/disable functions using the high 32 bits of the 64-bit MSR. The low 32-bit act as a 32-bit event counter. Counting starts after software writes a non-zero value to one or more of the qualification bits in the upper 32-bits of the MSR. See Figure 30-43.

## PERFORMANCE MONITORING

Figure 30-43. MSR\_EFSB\_DRDYx, Addresses: 107D0H and 107D1H

- **IBUSQ Latency event** — This event accumulates weighted cycle counts for latency measurement of transactions in the iBUSQ unit. The count is enabled by setting MSR\_IFSB\_CTRL6[bit 26] to 1; the count freezes after software sets MSR\_IFSB\_CTRL6[bit 26] to 0. MSR\_IFSB\_CNTR7 acts as a 64-bit event counter for this event. See Figure 30-44.

Figure 30-44. MSR\_IFSB\_CTL6, Address: 107D2H;  
MSR\_IFSB\_CNTR7, Address: 107D3H

### 30.15 PERFORMANCE MONITORING ON L3 AND CACHING BUS CONTROLLER SUB-SYSTEMS

The Intel Xeon processor 7400 series and Dual-Core Intel Xeon processor 7100 series employ a distinct L3/caching bus controller sub-system. These sub-system have a unique set of performance monitoring capability and programming interfaces that are largely common between these two processor families.

Intel Xeon processor 7400 series are based on 45nm enhanced Intel Core microarchitecture. The CPUID signature is indicated by DisplayFamily\_DisplayModel value of 06\_1DH (see CPUID instruction in Chapter 3, "Instruction Set Reference, A-M" in the *Intel® 64 and IA-32 Architectures Software Developer's Manual, Volume 2A*). Intel Xeon processor 7400 series have six processor cores that share an L3 cache.

Dual-Core Intel Xeon processor 7100 series are based on Intel NetBurst microarchitecture, have a CPUID signature of family [0FH], model [06H] and a unified L3 cache shared between two cores. Each core in an Intel Xeon processor 7100 series supports Intel Hyper-Threading Technology, providing two logical processors per core.

Both Intel Xeon processor 7400 series and Intel Xeon processor 7100 series support multi-processor configurations using system bus interfaces. In Intel Xeon processor 7400 series, the L3/caching bus controller sub-system provides three Simple Direct Interface (SDI) to service transactions originated the XQ-replacement SDI logic in each dual-core modules. In Intel Xeon processor 7100 series, the IOQ logic in each processor core is replaced with a Simple Direct Interface (SDI) logic. The L3 cache is

## PERFORMANCE MONITORING

connected between the system bus and the SDI through additional control logic. See Figure 30-45 for the block configuration of six processor cores and the L3/Caching bus controller sub-system in Intel Xeon processor 7400 series. Figure 30-45 shows the block configuration of two processor cores (four logical processors) and the L3/Caching bus controller sub-system in Intel Xeon processor 7100 series.

Figure 30-45. Block Diagram of Intel Xeon Processor 7400 Series

Almost all of the performance monitoring capabilities available to processor cores with the same CPUID signatures (see Section 30.1 and Section 30.10) apply to Intel Xeon processor 7100 series. The MSRs used by performance monitoring interface are shared between two logical processors in the same processor core.

The performance monitoring capabilities available to processor with `DisplayFamily_DisplayModel` signature `06_17H` also apply to Intel Xeon processor 7400 series. Each processor core provides its own set of MSRs for performance monitoring interface.

The `IOQ_allocation` and `IOQ_active_entries` events are not supported in Intel Xeon processor 7100 series and 7400 series. Additional performance monitoring capabilities applicable to the L3/caching bus controller sub-system are described in this section.

Figure 30-46. Block Diagram of Intel Xeon Processor 7100 Series

### 30.15.1 Overview of Performance Monitoring with L3/Caching Bus Controller

The facility for monitoring events consists of a set of dedicated model-specific registers (MSRs). There are eight event select/counting MSRs that are dedicated to counting events associated with specified microarchitectural conditions. Programming of these MSRs requires using RDMSR/WRMSR instructions with 64-bit values. In addition, an MSR MSR\_EMON\_L3\_GL\_CTL provides simplified interface to control freezing, resetting, re-enabling operation of any combination of these event select/counting MSRs.

The eight MSRs dedicated to count occurrences of specific conditions are further divided to count three sub-classes of microarchitectural conditions:

- Two MSRs (MSR\_EMON\_L3\_CTR\_CTL0 and MSR\_EMON\_L3\_CTR\_CTL1) are dedicated to counting GBSQ events. Up to two GBSQ events can be programmed and counted simultaneously.
- Two MSRs (MSR\_EMON\_L3\_CTR\_CTL2 and MSR\_EMON\_L3\_CTR\_CTL3) are dedicated to counting GSNPQ events. Up to two GSNPQ events can be programmed and counted simultaneously.

## PERFORMANCE MONITORING

- Four MSRs (MSR\_EMON\_L3\_CTR\_CTL4, MSR\_EMON\_L3\_CTR\_CTL5, MSR\_EMON\_L3\_CTR\_CTL6, and MSR\_EMON\_L3\_CTR\_CTL7) are dedicated to counting external bus operations.

The bit fields in each of eight MSRs share the following common characteristics:

- Bits 63:32 is the event control field that includes an event mask and other bit fields that control counter operation. The event mask field specifies details of the microarchitectural condition, and its definition differs across GBSQ, GSNPQ, FSB.
- Bits 31:0 is the event count field. If the specified condition is met during each relevant clock domain of the event logic, the matched condition signals the counter logic to increment the associated event count field. The lower 32-bits of these 8 MSRs at addresses 107CC through 107D3 are treated as 32 bit performance counter registers.

In Dual-Core Intel Xeon processor 7100 series, the uncore performance counters can be accessed using RDPMC instruction with the index starting from 18 through 25. The EDX register returns zero when reading these 8 PMCs.

In Intel Xeon processor 7400 series, RDPMC with ECX between 2 and 9 can be used to access the eight uncore performance counter/control registers.

### 30.15.2 GBSQ Event Interface

The layout of MSR\_EMON\_L3\_CTR\_CTL0 and MSR\_EMON\_L3\_CTR\_CTL1 is given in Figure 30-47. Counting starts after software writes a non-zero value to one or more of the upper 32 bits.

The event mask field (bits 58:32) consists of the following eight attributes:

- Agent\_Select (bits 35:32): The definition of this field differs slightly between Intel Xeon processor 7100 and 7400.

For Intel Xeon processor 7100 series, each bit specifies a logical processor in the physical package. The lower two bits corresponds to two logical processors in the first processor core, the upper two bits corresponds to two logical processors in the second processor core. OFH encoding matches transactions from any logical processor.

For Intel Xeon processor 7400 series, each bit of [34:32] specifies the SDI logic of a dual-core module as the originator of the transaction. A value of 0111B in bits [35:32] specifies transaction from any processor core.

Figure 30-47. MSR\_EMON\_L3\_CTR\_CTL0/1, Addresses: 107CCH/107CDH

- Data\_Flow (bits 37:36): Bit 36 specifies demand transactions, bit 37 specifies prefetch transactions.
- Type\_Match (bits 43:38): Specifies transaction types. If all six bits are set, event count will include all transaction types.
- Snoop\_Match: (bits 46:44): The three bits specify (in ascending bit position) clean snoop result, HIT snoop result, and HITM snoop results respectively.
- L3\_State (bits 53:47): Each bit specifies an L2 coherency state.
  - For Intel Xeon processor 7100 series,
    - 00B: Match transactions from any core in the physical package
    - 01B: Match transactions from this core only
    - 10B: Match transactions from the other core in the physical package
    - 11B: Match transaction from both cores in the physical package
  - For Intel Xeon processor 7400 series,
    - 00B: Match transactions from any dual-core module in the physical package
- Core\_Module\_Select (bits 55:54): The valid encodings for L3 lookup differ slightly between Intel Xeon processor 7100 and 7400.

## PERFORMANCE MONITORING

- 01B: Match transactions from this dual-core module only
- 10B: Match transactions from either one of the other two dual-core modules in the physical package
- 11B: Match transaction from more than one dual-core modules in the physical package
- Fill\_Eviction (bits 57:56): The valid encodings are
  - 00B: Match any transactions
  - 01B: Match transactions that fill L3
  - 10B: Match transactions that fill L3 without an eviction
  - 11B: Match transaction fill L3 with an eviction
- Cross\_Snoop (bit 58): The encodings are
  - 0B: Match any transactions
  - 1B: Match cross snoop transactions

For each counting clock domain, if all eight attributes match, event logic signals to increment the event count field.

### 30.15.3 GSNPQ Event Interface

The layout of MSR\_EMON\_L3\_CTR\_CTL2 and MSR\_EMON\_L3\_CTR\_CTL3 is given in Figure 30-48. Counting starts after software writes a non-zero value to one or more of the upper 32 bits.

The event mask field (bits 58:32) consists of the following six attributes:

- Agent\_Select (bits 37:32): The definition of this field differs slightly between Intel Xeon processor 7100 and 7400.
- For Intel Xeon processor 7100 series, each of the lowest 4 bits specifies a logical processor in the physical package. The lowest two bits corresponds to two logical processors in the first processor core, the next two bits corresponds to two logical processors in the second processor core. Bit 36 specifies other symmetric agent transactions. Bit 37 specifies central agent transactions. 3FH encoding matches transactions from any logical processor.

For Intel Xeon processor 7400 series, each of the lowest 3 bits specifies a dual-core module in the physical package. Bit 37 specifies central agent transactions.

- Type\_Match (bits 43:38): Specifies transaction types. If all six bits are set, event count will include any transaction types.
- Snoop\_Match: (bits 46:44): The three bits specify (in ascending bit position) clean snoop result, HIT snoop result, and HITM snoop results respectively.
- L2\_State (bits 53:47): Each bit specifies an L3 coherency state.
- Core\_Module\_Select (bits 56:54): Bit 56 enables Core\_Module\_Select matching. If bit 56 is clear, Core\_Module\_Select encoding is ignored. The valid encodings for

the lower two bits (bit 55, 54) differ slightly between Intel Xeon processor 7100 and 7400.

For Intel Xeon processor 7100 series, if bit 56 is set, the valid encodings for the lower two bits (bit 55, 54) are

- 00B: Match transactions from only one core (irrespective which core) in the physical package
- 01B: Match transactions from this core and not the other core
- 10B: Match transactions from the other core in the physical package, but not this core
- 11B: Match transaction from both cores in the physical package

For Intel Xeon processor 7400 series, if bit 56 is set, the valid encodings for the lower two bits (bit 55, 54) are

- 00B: Match transactions from only one dual-core module (irrespective which module) in the physical package
- 01B: Match transactions from one or more dual-core modules.
- 10B: Match transactions from two or more dual-core modules.
- 11B: Match transaction from all three dual-core modules in the physical package
- Block\_Snoop (bit 57): specifies blocked snoop.

For each counting clock domain, if all six attributes match, event logic signals to increment the event count field.

## PERFORMANCE MONITORING

Figure 30-48. MSR\_EMON\_L3\_CTR\_CTL2/3, Addresses: 107CEH/107CFH

### 30.15.4 FSB Event Interface

The layout of MSR\_EMON\_L3\_CTR\_CTL4 through MSR\_EMON\_L3\_CTR\_CTL7 is given in Figure 30-49. Counting starts after software writes a non-zero value to one or more of the upper 32 bits.

The event mask field (bits 58:32) is organized as follows:

- Bit 58: must set to 1.
- FSB\_Submask (bits 57:32): Specifies FSB-specific sub-event mask.

The FSB sub-event mask defines a set of independent attributes. The event logic signals to increment the associated event count field if one of the attribute matches. Some of the sub-event mask bit counts durations. A duration event increments at most once per cycle.

Figure 30-49. MSR\_EMON\_L3\_CTR\_CTL4/5/6/7, Addresses: 107D0H-107D3H

### 30.15.4.1 FSB Sub-Event Mask Interface

- FSB\_type (bit 37: 32): Specifies different FSB transaction types originated from this physical package
- FSB\_L\_clear (bit 38): Count clean snoop results from any source for transaction originated from this physical package
- FSB\_L\_hit (bit 39): Count HIT snoop results from any source for transaction originated from this physical package
- FSB\_L\_hitm (bit 40): Count HITM snoop results from any source for transaction originated from this physical package
- FSB\_L\_defer (bit 41): Count DEFER responses to this processor's transactions
- FSB\_L\_retry (bit 42): Count RETRY responses to this processor's transactions
- FSB\_L\_snoop\_stall (bit 43): Count snoop stalls to this processor's transactions
- FSB\_DBSY (bit 44): Count DBSY assertions by this processor (without a concurrent DRDY)
- FSB\_DRDY (bit 45): Count DRDY assertions by this processor
- FSB\_BNR (bit 46): Count BNR assertions by this processor
- FSB\_IOQ\_empty (bit 47): Counts each bus clocks when the IOQ is empty
- FSB\_IOQ\_full (bit 48): Counts each bus clocks when the IOQ is full
- FSB\_IOQ\_active (bit 49): Counts each bus clocks when there is at least one entry in the IOQ

## PERFORMANCE MONITORING

- FSB\_WW\_data (bit 50): Counts back-to-back write transaction's data phase.
- FSB\_WW\_issue (bit 51): Counts back-to-back write transaction request pairs issued by this processor.
- FSB\_WR\_issue (bit 52): Counts back-to-back write-read transaction request pairs issued by this processor.
- FSB\_RW\_issue (bit 53): Counts back-to-back read-write transaction request pairs issued by this processor.
- FSB\_other\_DBSY (bit 54): Count DBSY assertions by another agent (without a concurrent DRDY)
- FSB\_other\_DRDY (bit 55): Count DRDY assertions by another agent
- FSB\_other\_snoop\_stall (bit 56): Count snoop stalls on the FSB due to another agent
- FSB\_other\_BNR (bit 57): Count BNR assertions from another agent

### 30.15.5 Common Event Control Interface

The MSR\_EMON\_L3\_GL\_CTL MSR provides simplified access to query overflow status of the GBSQ, GSNPO, FSB event counters. It also provides control bit fields to freeze, unfreeze, or reset those counters. The following bit fields are supported:

- GL\_freeze\_cmd (bit 0): Freeze the event counters specified by the GL\_event\_select field.
- GL\_unfreeze\_cmd (bit 1): Unfreeze the event counters specified by the GL\_event\_select field.
- GL\_reset\_cmd (bit 2): Clear the event count field of the event counters specified by the GL\_event\_select field. The event select field is not affected.
- GL\_event\_select (bit 23:16): Selects one or more event counters to subject to specified command operations indicated by bits 2:0. Bit 16 corresponds to MSR\_EMON\_L3\_CTR\_CTL0, bit 23 corresponds to MSR\_EMON\_L3\_CTR\_CTL7.
- GL\_event\_status (bit 55:48): Indicates the overflow status of each event counters. Bit 48 corresponds to MSR\_EMON\_L3\_CTR\_CTL0, bit 55 corresponds to MSR\_EMON\_L3\_CTR\_CTL7.

In the event control field (bits 63:32) of each MSR, if the saturate control (bit 59, see Figure 30-47 for example) is set, the event logic forces the value FFFF\_FFFFH into the event count field instead of incrementing it.

## 30.16 PERFORMANCE MONITORING (P6 FAMILY PROCESSOR)

The P6 family processors provide two 40-bit performance counters, allowing two types of events to be monitored simultaneously. These can either count events or

measure duration. When counting events, a counter increments each time a specified event takes place or a specified number of events takes place. When measuring duration, it counts the number of processor clocks that occur while a specified condition is true. The counters can count events or measure durations that occur at any privilege level.

Table A-22, Appendix A, lists the events that can be counted with the P6 family performance monitoring counters.

#### NOTE

The performance-monitoring events listed in Appendix A are intended to be used as guides for performance tuning. Counter values reported are not guaranteed to be accurate and should be used as a relative guide for tuning. Known discrepancies are documented where applicable.

The performance-monitoring counters are supported by four MSRs: the performance event select MSRs (PerfEvtSel0 and PerfEvtSel1) and the performance counter MSRs (PerfCtr0 and PerfCtr1). These registers can be read from and written to using the RDMSR and WRMSR instructions, respectively. They can be accessed using these instructions only when operating at privilege level 0. The PerfCtr0 and PerfCtr1 MSRs can be read from any privilege level using the RDPMC (read performance-monitoring counters) instruction.

#### NOTE

The PerfEvtSel0, PerfEvtSel1, PerfCtr0, and PerfCtr1 MSRs and the events listed in Table A-22 are model-specific for P6 family processors. They are not guaranteed to be available in other IA-32 processors.

### 30.16.1 PerfEvtSel0 and PerfEvtSel1 MSRs

The PerfEvtSel0 and PerfEvtSel1 MSRs control the operation of the performance-monitoring counters, with one register used to set up each counter. They specify the events to be counted, how they should be counted, and the privilege levels at which counting should take place. Figure 30-50 shows the flags and fields in these MSRs.

The functions of the flags and fields in the PerfEvtSel0 and PerfEvtSel1 MSRs are as follows:

- **Event select field (bits 0 through 7)** — Selects the event logic unit to detect certain microarchitectural conditions (see Table A-22, for a list of events and their 8-bit codes).
- **Unit mask (UMASK) field (bits 8 through 15)** — Further qualifies the event logic unit selected in the event select field to detect a specific microarchitectural condition. For example, for some cache events, the mask is used as a MESI-protocol qualifier of cache states (see Table A-22).

## PERFORMANCE MONITORING

Figure 30-50. PerfEvtSel0 and PerfEvtSel1 MSRs

- **USR (user mode) flag (bit 16)** — Specifies that events are counted only when the processor is operating at privilege levels 1, 2 or 3. This flag can be used in conjunction with the OS flag.
  - **OS (operating system mode) flag (bit 17)** — Specifies that events are counted only when the processor is operating at privilege level 0. This flag can be used in conjunction with the USR flag.
  - **E (edge detect) flag (bit 18)** — Enables (when set) edge detection of events. The processor counts the number of deasserted to asserted transitions of any condition that can be expressed by the other fields. The mechanism is limited in that it does not permit back-to-back assertions to be distinguished. This mechanism allows software to measure not only the fraction of time spent in a particular state, but also the average length of time spent in such a state (for example, the time spent waiting for an interrupt to be serviced).
  - **PC (pin control) flag (bit 19)** — When set, the processor toggles the PM*i* pins and increments the counter when performance-monitoring events occur; when clear, the processor toggles the PM*i* pins when the counter overflows. The toggling of a pin is defined as assertion of the pin for a single bus clock followed by deassertion.
  - **INT (APIC interrupt enable) flag (bit 20)** — When set, the processor generates an exception through its local APIC on counter overflow.
  - **EN (Enable Counters) Flag (bit 22)** — This flag is only present in the PerfEvtSel0 MSR. When set, performance counting is enabled in both performance-monitoring counters; when clear, both counters are disabled.
  - **INV (invert) flag (bit 23)** — Inverts the result of the counter-mask comparison when set, so that both greater than and less than comparisons can be made.

- **Counter mask (CMASK) field (bits 24 through 31)** — When nonzero, the processor compares this mask to the number of events counted during a single cycle. If the event count is greater than or equal to this mask, the counter is incremented by one. Otherwise the counter is not incremented. This mask can be used to count events only if multiple occurrences happen per clock (for example, two or more instructions retired per clock). If the counter-mask field is 0, then the counter is incremented each cycle by the number of events that occurred that cycle.

### 30.16.2 PerfCtr0 and PerfCtr1 MSRs

The performance-counter MSRs (PerfCtr0 and PerfCtr1) contain the event or duration counts for the selected events being counted. The RDPMC instruction can be used by programs or procedures running at any privilege level and in virtual-8086 mode to read these counters. The PCE flag in control register CR4 (bit 8) allows the use of this instruction to be restricted to only programs and procedures running at privilege level 0.

The RDPMC instruction is not serializing or ordered with other instructions. Thus, it does not necessarily wait until all previous instructions have been executed before reading the counter. Similarly, subsequent instructions may begin execution before the RDPMC instruction operation is performed.

Only the operating system, executing at privilege level 0, can directly manipulate the performance counters, using the RDMSR and WRMSR instructions. A secure operating system would clear the PCE flag during system initialization to disable direct user access to the performance-monitoring counters, but provide a user-accessible programming interface that emulates the RDPMC instruction.

The WRMSR instruction cannot arbitrarily write to the performance-monitoring counter MSRs (PerfCtr0 and PerfCtr1). Instead, the lower-order 32 bits of each MSR may be written with any value, and the high-order 8 bits are sign-extended according to the value of bit 31. This operation allows writing both positive and negative values to the performance counters.

### 30.16.3 Starting and Stopping the Performance-Monitoring Counters

The performance-monitoring counters are started by writing valid setup information in the PerfEvtSel0 and/or PerfEvtSel1 MSRs and setting the enable counters flag in the PerfEvtSel0 MSR. If the setup is valid, the counters begin counting following the execution of a WRMSR instruction that sets the enable counter flag. The counters can be stopped by clearing the enable counters flag or by clearing all the bits in the PerfEvtSel0 and PerfEvtSel1 MSRs. Counter 1 alone can be stopped by clearing the PerfEvtSel1 MSR.

### 30.16.4 Event and Time-Stamp Monitoring Software

To use the performance-monitoring counters and time-stamp counter, the operating system needs to provide an event-monitoring device driver. This driver should include procedures for handling the following operations:

- Feature checking
- Initialize and start counters
- Stop counters
- Read the event counters
- Read the time-stamp counter

The event monitor feature determination procedure must check whether the current processor supports the performance-monitoring counters and time-stamp counter. This procedure compares the family and model of the processor returned by the CPUID instruction with those of processors known to support performance monitoring. (The Pentium and P6 family processors support performance counters.) The procedure also checks the MSR and TSC flags returned to register EDX by the CPUID instruction to determine if the MSRs and the RDTSC instruction are supported.

The initialize and start counters procedure sets the PerfEvtSel0 and/or PerfEvtSel1 MSRs for the events to be counted and the method used to count them and initializes the counter MSRs (PerfCtr0 and PerfCtr1) to starting counts. The stop counters procedure stops the performance counters (see Section 30.16.3, "Starting and Stopping the Performance-Monitoring Counters").

The read counters procedure reads the values in the PerfCtr0 and PerfCtr1 MSRs, and a read time-stamp counter procedure reads the time-stamp counter. These procedures would be provided in lieu of enabling the RDTSC and RDPMC instructions that allow application code to read the counters.

### 30.16.5 Monitoring Counter Overflow

The P6 family processors provide the option of generating a local APIC interrupt when a performance-monitoring counter overflows. This mechanism is enabled by setting the interrupt enable flag in either the PerfEvtSel0 or the PerfEvtSel1 MSR. The primary use of this option is for statistical performance sampling.

To use this option, the operating system should do the following things on the processor for which performance events are required to be monitored:

- Provide an interrupt vector for handling the counter-overflow interrupt.
- Initialize the APIC PERF local vector entry to enable handling of performance-monitor counter overflow events.
- Provide an entry in the IDT that points to a stub exception handler that returns without executing any instructions.
- Provide an event monitor driver that provides the actual interrupt handler and modifies the reserved IDT entry to point to its interrupt routine.

When interrupted by a counter overflow, the interrupt handler needs to perform the following actions:

- Save the instruction pointer (EIP register), code-segment selector, TSS segment selector, counter values and other relevant information at the time of the interrupt.
- Reset the counter to its initial setting and return from the interrupt.

An event monitor application utility or another application program can read the information collected for analysis of the performance of the profiled application.

## 30.17 PERFORMANCE MONITORING (PENTIUM PROCESSORS)

The Pentium processor provides two 40-bit performance counters, which can be used to count events or measure duration. The counters are supported by three MSRs: the control and event select MSR (CESR) and the performance counter MSRs (CTR0 and CTR1). These can be read from and written to using the RDMSR and WRMSR instructions, respectively. They can be accessed using these instructions only when operating at privilege level 0.

Each counter has an associated external pin (PM0/BP0 and PM1/BP1), which can be used to indicate the state of the counter to external hardware.

### NOTES

The CESR, CTR0, and CTR1 MSRs and the events listed in Table A-23 are model-specific for the Pentium processor.

The performance-monitoring events listed in Appendix A are intended to be used as guides for performance tuning. Counter values reported are not guaranteed to be accurate and should be used as a relative guide for tuning. Known discrepancies are documented where applicable.

### 30.17.1 Control and Event Select Register (CESR)

The 32-bit control and event select MSR (CESR) controls the operation of performance-monitoring counters CTR0 and CTR1 and the associated pins (see Figure 30-51). To control each counter, the CESR register contains a 6-bit event select field (ES0 and ES1), a pin control flag (PC0 and PC1), and a 3-bit counter control field (CC0 and CC1). The functions of these fields are as follows:

- **ES0 and ES1 (event select) fields (bits 0-5, bits 16-21)** — Selects (by entering an event code in the field) up to two events to be monitored. See Table A-23 for a list of available event codes.

## PERFORMANCE MONITORING

Figure 30-51. CESR MSR (Pentium Processor Only)

- **CC0 and CC1 (counter control) fields (bits 6-8, bits 22-24)** — Controls the operation of the counter. Control codes are as follows:

- 000 — Count nothing (counter disabled)
- 001 — Count the selected event while CPL is 0, 1, or 2
- 010 — Count the selected event while CPL is 3
- 011 — Count the selected event regardless of CPL
- 100 — Count nothing (counter disabled)
- 101 — Count clocks (duration) while CPL is 0, 1, or 2
- 110 — Count clocks (duration) while CPL is 3
- 111 — Count clocks (duration) regardless of CPL

The highest order bit selects between counting events and counting clocks (duration); the middle bit enables counting when the CPL is 3; and the low-order bit enables counting when the CPL is 0, 1, or 2.

- **PC0 and PC1 (pin control) flags (bits 9, 25)** — Selects the function of the external performance-monitoring counter pin (PM0/BP0 and PM1/BP1). Setting one of these flags to 1 causes the processor to assert its associated pin when the counter has overflowed; setting the flag to 0 causes the pin to be asserted when the counter has been incremented. These flags permit the pins to be individually programmed to indicate the overflow or incremented condition. The external signalling of the event on the pins will lag the internal event by a few clocks as the signals are latched and buffered.

While a counter need not be stopped to sample its contents, it must be stopped and cleared or preset before switching to a new event. It is not possible to set one counter separately. If only one event needs to be changed, the CESR register must

be read, the appropriate bits modified, and all bits must then be written back to CESR. At reset, all bits in the CESR register are cleared.

### 30.17.2 Use of the Performance-Monitoring Pins

When performance-monitor pins PM0/BP0 and/or PM1/BP1 are configured to indicate when the performance-monitor counter has incremented and an “occurrence event” is being counted, the associated pin is asserted (high) each time the event occurs. When a “duration event” is being counted, the associated PM pin is asserted for the entire duration of the event. When the performance-monitor pins are configured to indicate when the counter has overflowed, the associated PM pin is asserted when the counter has overflowed.

When the PM0/BP0 and/or PM1/BP1 pins are configured to signal that a counter has incremented, it should be noted that although the counters may increment by 1 or 2 in a single clock, the pins can only indicate that the event occurred. Moreover, since the internal clock frequency may be higher than the external clock frequency, a single external clock may correspond to multiple internal clocks.

A “count up to” function may be provided when the event pin is programmed to signal an overflow of the counter. Because the counters are 40 bits, a carry out of bit 39 indicates an overflow. A counter may be preset to a specific value less than  $2^{40} - 1$ . After the counter has been enabled and the prescribed number of events has transpired, the counter will overflow.

Approximately 5 clocks later, the overflow is indicated externally and appropriate action, such as signaling an interrupt, may then be taken.

The PM0/BP0 and PM1/BP1 pins also serve to indicate breakpoint matches during in-circuit emulation, during which time the counter increment or overflow function of these pins is not available. After RESET, the PM0/BP0 and PM1/BP1 pins are configured for performance monitoring, however a hardware debugger may reconfigure these pins to indicate breakpoint matches.

### 30.17.3 Events Counted

Events that performance-monitoring counters can be set to count and record (using CTR0 and CTR1) are divided in two categories: occurrence and duration:

- **Occurrence events** — Counts are incremented each time an event takes place. If PM0/BP0 or PM1/BP1 pins are used to indicate when a counter increments, the pins are asserted each clock counters increment. But if an event happens twice in one clock, the counter increments by 2 (the pins are asserted only once).
- **Duration events** — Counters increment the total number of clocks that the condition is true. When used to indicate when counters increment, PM0/BP0 and/or PM1/BP1 pins are asserted for the duration.

## PERFORMANCE MONITORING

## APPENDIX A

# PERFORMANCE-MONITORING EVENTS

---

This appendix lists the performance-monitoring events that can be monitored with the Intel 64 or IA-32 processors. The ability to monitor performance events and the events that can be monitored in these processors are mostly model-specific, except for architectural performance events, described in Section A.1.

Non-architectural performance events (i.e. model-specific events) are listed for each generation of microarchitecture:

- Section A.2 - Processors based on Intel® microarchitecture code name Sandy Bridge
- Section A.3 - Processors based on Intel® microarchitecture code name Nehalem
- Section A.4 - Processors based on Intel® microarchitecture code name Westmere
- Section A.5 - Processors based on Enhanced Intel® Core™ microarchitecture
- Section A.6 - Processors based on Intel® Core™ microarchitecture
- Section A.7 - Processors based on Intel® Atom™ microarchitecture
- Section A.8 - Intel® Core™ Solo and Intel® Core™ Duo processors
- Section A.9 - Processors based on Intel NetBurst® microarchitecture
- Section A.10 - Pentium® M family processors
- Section A.11 - P6 family processors
- Section A.12 - Pentium® processors

### NOTE

These performance-monitoring events are intended to be used as guides for performance tuning. The counter values reported by the performance-monitoring events are approximate and believed to be useful as relative guides for tuning software. Known discrepancies are documented where applicable.

## A.1 ARCHITECTURAL PERFORMANCE-MONITORING EVENTS

Architectural performance events are introduced in Intel Core Solo and Intel Core Duo processors. They are also supported on processors based on Intel Core microarchitecture. Table A-1 lists pre-defined architectural performance events that can be configured using general-purpose performance counters and associated event-select registers.

## PERFORMANCE-MONITORING EVENTS

Table A-1. Architectural Performance Events

| Event Num. | Event Mask Mnemonic        | Umask Value | Description                                   | Comment                         |
|------------|----------------------------|-------------|-----------------------------------------------|---------------------------------|
| 3CH        | UnHalted Core Cycles       | 00H         | Unhalted core cycles                          |                                 |
| 3CH        | UnHalted Reference Cycles  | 01H         | Unhalted reference cycles                     | Measures bus cycle <sup>1</sup> |
| COH        | Instruction Retired        | 00H         | Instruction retired                           |                                 |
| 2EH        | LLC Reference              | 4FH         | Last level cache references                   |                                 |
| 2EH        | LLC Misses                 | 41H         | Last level cache misses                       |                                 |
| C4H        | Branch Instruction Retired | 00H         | Branch instruction at retirement              |                                 |
| C5H        | Branch Misses Retired      | 00H         | Mispredicted Branch Instruction at retirement |                                 |

NOTES:

1. Implementation of this event in Intel Core 2 processor family, Intel Core Duo, and Intel Core Solo processors measures bus clocks.

## A.2 PERFORMANCE MONITORING EVENTS FOR INTEL® CORE™ PROCESSOR 2XXX SERIES

Second generation Intel® Core™ Processor 2xxx Series are based on the Intel microarchitecture code name Sandy Bridge. They support the architectural and non-architectural performance-monitoring events listed in Table A-1 and Table A-2. The events in Table A-2 apply to processors with CPUID signature of DisplayFamily\_DisplayModel encoding with the following values: 06\_2AH.

Table A-2. Non-Architectural Performance Events In the Processor Core for Intel Core i7, i5, i3 Processors 2xxx Series

| Event Num. | Umask Value | Event Mask Mnemonic      | Description                                                              | Comment |
|------------|-------------|--------------------------|--------------------------------------------------------------------------|---------|
| 03H        | 01H         | LD_BLOCKS.DATA_U_NKNOWN  | blocked loads due to store buffer blocks with unknown data.              |         |
| 03H        | 02H         | LD_BLOCKS.STORE_F_ORWARD | loads blocked by overlapping with store buffer that cannot be forwarded. |         |
| 03H        | 08H         | LD_BLOCKS.NO_SR          | # of Split loads blocked due to resource not available.                  |         |
| 03H        | 10H         | LD_BLOCKS.ALL_BLOCK      | Number of cases where any load is blocked but has no DCU miss.           |         |

**Table A-2. Non-Architectural Performance Events In the Processor Core for Intel Core i7, i5, i3 Processors 2xxx Series**

| Event Num. | Umask Value | Event Mask Mnemonic                          | Description                                                                                                                                                                                   | Comment                                        |

## PERFORMANCE-MONITORING EVENTS

**Table A-2. Non-Architectural Performance Events In the Processor Core for Intel Core i7, i5, i3 Processors 2xxx Series**

| Event Num. | Umask Value | Event Mask Mnemonic                    | Description                                                                                                    | Comment |
|------------|-------------|----------------------------------------|----------------------------------------------------------------------------------------------------------------|---------|
| 10H        | 20H         | FP_COMP_OPS_EXE. SSE_FP_SCALAR_SIN GLE | Counts number of SSE* single precision FP scalar uops executed.                                                |         |
| 10H        | 40H         | FP_COMP_OPS_EXE. SSE_PACKED SINGLE     | Counts number of SSE* single precision FP packed uops executed.                                                |         |
| 10H        | 80H         | FP_COMP_OPS_EXE. SSE_SCALAR_DOUBL E    | Counts number of SSE* double precision FP scalar uops executed.                                                |         |
| 11H        | 01H         | SIMD_FP_256.PACKED_SINGLE              | Counts 256-bit packed single-precision floating-point instructions                                             |         |
| 11H        | 02H         | SIMD_FP_256.PACKED_DOUBLE              | Counts 256-bit packed double-precision floating-point instructions                                             |         |
| 14H        | 01H         | ARITH.FPU_DIV_ACT IVE                  | Cycles that the divider is active, includes INT and FP. Set 'edge =1, cmask=1' to count the number of divides. |         |
| 17H        | 01H         | INSTS_WRITTEN_TO _IQ.INSTS             | Counts the number of instructions written into the IQ every cycle.                                             |         |
| 24H        | 01H         | L2_RQSTS.DEMAND_ DATA_RD_HIT           | Demand Data Read requests that hit L2 cache                                                                    |         |
| 24H        | 03H         | L2_RQSTS.ALL_DEM AND_DATA_RD           | Counts any demand and L1 HW prefetch data load requests to L2.                                                 |         |
| 24H        | 04H         | L2_RQSTS.RFO_HITS                      | Counts the number of store RFO requests that hit the L2 cache.                                                 |         |
| 24H        | 08H         | L2_RQSTS.RFO_MISS                      | Counts the number of store RFO requests that miss the L2 cache.                                                |         |
| 24H        | 0CH         | L2_RQSTS.ALL_RFO                       | Counts all L2 store RFO requests.                                                                              |         |
| 24H        | 10H         | L2_RQSTS.CODE_RD _HIT                  | Number of instruction fetches that hit the L2 cache.                                                           |         |
| 24H        | 20H         | L2_RQSTS.CODE_RD _MISS                 | Number of instruction fetches that missed the L2 cache.                                                        |         |
| 24H        | 30H         | L2_RQSTS.ALL_COD E_RD                  | Counts all L2 code requests.                                                                                   |         |
| 24H        | 40H         | L2_RQSTS.PF_HIT                        | Requests from L2 Hardware prefetcher that hit L2.                                                              |         |
| 24H        | 80H         | L2_RQSTS.PF_MISS                       | Requests from L2 Hardware prefetcher that missed L2.                                                           |         |

## PERFORMANCE-MONITORING EVENTS

**Table A-2. Non-Architectural Performance Events In the Processor Core for Intel Core i7, i5, i3 Processors 2xxx Series**

| Event Num. | Umask Value | Event Mask Mnemonic                    | Description                                                                                                                                                                                                                              | Comment                                        |
|------------|-------------|----------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------|
| 24H        | COH         | L2_RQSTS.ALL_PF                        | Any requests from L2 Hardware prefetchers                                                                                                                                                                                                |                                                |
| 27H        | 01H         | L2_STORE_LOCK_RQ STS.MISS              | RFOs that miss cache lines                                                                                                                                                                                                               |                                                |
| 27H        | 04H         | L2_STORE_LOCK_RQ STS.HIT_E             | RFOs that hit cache lines in E state                                                                                                                                                                                                     |                                                |
| 27H        | 08H         | L2_STORE_LOCK_RQ STS.HIT_M             | RFOs that hit cache lines in M state                                                                                                                                                                                                     |                                                |
| 27H        | 0FH         | L2_STORE_LOCK_RQ STS.ALL               | RFOs that access cache lines in any state                                                                                                                                                                                                |                                                |
| 28H        | 04H         | L2_L1D_WB_RQSTS. HIT_E                 | Not rejected writebacks from L1D to L2 cache lines in E state.                                                                                                                                                                           |                                                |
| 28H        | 08H         | L2_L1D_WB_RQSTS. HIT_M                 | Not rejected writebacks from L1D to L2 cache lines in M state.                                                                                                                                                                           |                                                |
| 2EH        | 4FH         | LONGEST_LAT_CACH E.REFERENCE           | This event counts requests originating from the core that reference a cache line in the last level cache.                                                                                                                                | see Table A-1                                  |
| 2EH        | 41H         | LONGEST_LAT_CACH E.MISS                | This event counts each cache miss condition for references to the last level cache.                                                                                                                                                      | see Table A-1                                  |
| 3CH        | 00H         | CPU_CLK_UNHALTED .THREAD_P             | Counts the number of thread cycles while the thread is not in a halt state. The thread enters the halt state when it is running the HLT instruction. The core frequency may change from time to time due to power or thermal throttling. | see Table A-1                                  |
| 3CH        | 01H         | CPU_CLK_THREAD_ UNHALTED.REF_XCLK      | Increments at the frequency of XCLK (100 MHz) when not halted.                                                                                                                                                                           | see Table A-1                                  |
| 48H        | 01H         | L1D_PEND_MISS.PE NDING                 | Increments the number of outstanding L1D misses every cycle. Set Cmask = 1 and Edge =1 to count occurrences.                                                                                                                             | Counter 2 only; Set Cmask = 1 to count cycles. |
| 49H        | 01H         | DTLB_STORE_MISSE S.MISS_CAUSES_A_ WALK | Miss in all TLB levels causes an page walk of any page size (4K/2M/4M/1G).                                                                                                                                                               |                                                |

## PERFORMANCE-MONITORING EVENTS

| 49H        | 02H         | DTLB_STORE_MISSE S.WALK_COMPLETED   | Miss in all TLB levels causes a page walk that completes of any page size (4K/2M/4M/1G).                                                                                                          |                                                                       |
| 49H        | 04H         | DTLB_STORE_MISSE S.WALK_DURATION    | Cycles PMH is busy with this walk.                                                                                                                                                                |                                                                       |
| 49H        | 10H         | DTLB_STORE_MISSE S.STLB_HIT         | Store operations that miss the first TLB level but hit the second and do not cause page walks                                                                                                     |                                                                       |
| 4CH        | 01H         | LOAD_HIT_PRE.SW_PF                  | Not SW-prefetch load dispatches that hit fill buffer allocated for S/W prefetch.                                                                                                                  |                                                                       |
| 4CH        | 02H         | LOAD_HIT_PRE.HW_PF                  | Not SW-prefetch load dispatches that hit fill buffer allocated for H/W prefetch.                                                                                                                  |                                                                       |
| 4EH        | 02H         | HW_PRE_REQ.DL1_MISS                 | Hardware Prefetch requests that miss the L1D cache. A request is being counted each time it access the cache & miss it, including if a block is applicable or if hit the Fill Buffer for example. | This accounts for both L1 streamer and IP-based (IPP) HW prefetchers. |
| 51H        | 01H         | L1D.REPLACEMENT                     | Counts the number of lines brought into the L1 data cache.                                                                                                                                        |                                                                       |
| 51H        | 02H         | L1D.ALLOCATED_IN_M                  | Counts the number of allocations of modified L1D cache lines.                                                                                                                                     |                                                                       |
| 51H        | 04H         | L1D.EVICTION                        | Counts the number of modified lines evicted from the L1 data cache due to replacement.                                                                                                            |                                                                       |
| 51H        | 08H         | L1D.ALL_M_REPLACEMENT               | Cache lines in M state evicted out of L1D due to Snoop HitM or dirty line replacement                                                                                                             |                                                                       |
| 59H        | 20H         | PARTIAL_RAT_STALL S.FLAGS_MERGE_UOP | Increments the number of flags-merge uops in flight each cycle. Set Cmask = 1 to count cycles.                                                                                                    |                                                                       |
| 59H        | 40H         | PARTIAL_RAT_STALL S.SLOW_LEA_WINDOW | Cycles with at least one slow LEA uop allocated.                                                                                                                                                  |                                                                       |
| 59H        | 80H         | PARTIAL_RAT_STALL S.MUL_SINGLE_UOP  | Number of Multiply packed/scalar single precision uops allocated.                                                                                                                                 |                                                                       |

**Table A-2. Non-Architectural Performance Events In the Processor Core for Intel Core i7, i5, i3 Processors 2xxx Series**

| Event Num. | Umask Value | Event Mask Mnemonic                              | Description                                                                                        | Comment                       |
|------------|-------------|--------------------------------------------------|----------------------------------------------------------------------------------------------------|-------------------------------|
| 5BH        | 0CH         | RESOURCE_STALLS2.ALL_FL_EMPTY                    | Cycles stalled due to free list empty                                                              |                               |
| 5BH        | 0FH         | RESOURCE_STALLS2.ALL_PRF_CONTROL                 | Cycles stalled due to control structures full for physical registers                               |                               |
| 5BH        | 40H         | RESOURCE_STALLS2.BOB_FULL                        | Cycles Allocator is stalled due Branch Order Buffer.                                               |                               |
| 5BH        | 4FH         | RESOURCE_STALLS2.OOO_RSRC                        | Cycles stalled due to out of order resources full                                                  |                               |
| 5CH        | 01H         | CPL_CYCLES.RING0                                 | Unhalted core cycles when the thread is in ring 0                                                  | Use Edge to count transition  |
| 5CH        | 02H         | CPL_CYCLES.RING123                               | Unhalted core cycles when the thread is not in ring 0                                              |                               |
| 5EH        | 01H         | RS_EVENTS.EMPTY_CYCLES                           | Cycles the RS is empty for the thread.                                                             |                               |
| 60H        | 01H         | OFFCORE_REQUESTS_OUTSTANDING.DEMAND_DATA_RD      | Offcore outstanding Demand Data Read transactions in SQ to uncore. Set Cmask=1 to count cycles.    |                               |
| 60H        | 04H         | OFFCORE_REQUESTS_OUTSTANDING.DEMAND_RFO          | Offcore outstanding RFO store transactions in SQ to uncore. Set Cmask=1 to count cycles.           |                               |
| 60H        | 08H         | OFFCORE_REQUESTS_OUTSTANDING.ACCESSIONAL_DATA_RD | Offcore outstanding cacheable data read transactions in SQ to uncore. Set Cmask=1 to count cycles. |                               |
| 63H        | 01H         | LOCK_CYCLES.SPLIT_LOCK_UC_LOCK_DURATION          | Cycles in which the L1D and L2 are locked, due to a UC lock or split lock.                         |                               |
| 63H        | 02H         | LOCK_CYCLES.CACHE_LOCK_DURATION                  | Cycles in which the L1D is locked.                                                                 |                               |
| 79H        | 02H         | IDQ.EMPTY                                        | Counts cycles the IDQ is empty.                                                                    |                               |
| 79H        | 04H         | IDQ.MITE_UOPS                                    | Increment each cycle # of uops delivered to IDQ from MITE path. Set Cmask = 1 to count cycles.     | Can combine Umask 04H and 20H |
| 79H        | 08H         | IDQ.DSB_UOPS                                     | Increment each cycle. # of uops delivered to IDQ from DSB path. Set Cmask = 1 to count cycles.     | Can combine Umask 08H and 10H |

## PERFORMANCE-MONITORING EVENTS

**Table A-2. Non-Architectural Performance Events In the Processor Core for Intel Core i7, i5, i3 Processors 2xxx Series**

| Event Num. | Umask Value | Event Mask Mnemonic                    | Description                                                                                                                                                     | Comment                            |
|------------|-------------|----------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------|
| 79H        | 10H         | IDQ.MS_DSB_UOPS                        | Increment each cycle # of uops delivered to IDQ when MS busy by DSB. Set Cmask = 1 to count cycles MS is busy. Set Cmask=1 and Edge =1 to count MS activations. | Can combine Umask 08H and 10H      |
| 79H        | 20H         | IDQ.MS_MITE_UOPS                       | Increment each cycle # of uops delivered to IDQ when MS is busy by MITE. Set Cmask = 1 to count cycles.                                                         | Can combine Umask 04H and 20H      |
| 79H        | 30H         | IDQ.MS_UOPS                            | Increment each cycle # of uops delivered to IDQ from MS by either DSB or MITE. Set Cmask = 1 to count cycles.                                                   | Can combine Umask 04H, 08H and 30H |
| 80H        | 02H         | ICACHE.MISSES                          | Number of Instruction Cache, Streaming Buffer and Victim Cache Misses. Includes UC accesses.                                                                    |                                    |
| 85H        | 01H         | ITLB_MISSES.MISS_C_AUSES_A_WALK        | Misses in all ITLB levels that cause page walks                                                                                                                 |                                    |
| 85H        | 02H         | ITLB_MISSES.WALK_COMPLETED             | Misses in all ITLB levels that cause completed page walks                                                                                                       |                                    |
| 85H        | 04H         | ITLB_MISSES.WALK_DURATION              | Cycle PMH is busy with a walk.                                                                                                                                  |                                    |
| 85H        | 10H         | ITLB_MISSES.STLB_H_IT                  | Number of cache load STLB hits. No page walk.                                                                                                                   |                                    |
| 87H        | 01H         | ILD_STALL.LCP                          | Stalls caused by changing prefix length of the instruction.                                                                                                     |                                    |
| 87H        | 04H         | ILD_STALL.IQ_FULL                      | Stall cycles due to IQ is full.                                                                                                                                 |                                    |
| 88H        | 01H         | BR_INST_EXEC.COND                      | Qualify conditional near branch instructions executed, but not necessarily retired.                                                                             | Must combine with umask 40H, 80H   |
| 88H        | 02H         | BR_INST_EXEC.DIRECT_JMP                | Qualify all unconditional near branch instructions excluding calls and indirect branches.                                                                       | Must combine with umask 80H        |
| 88H        | 04H         | BR_INST_EXEC.INDIRECT_JMP_NON_CALL_RET | Qualify executed indirect near branch instructions that are not calls nor returns.                                                                              | Must combine with umask 80H        |
| 88H        | 08H         | BR_INST_EXEC.RETURN_NEAR               | Qualify indirect near branches that have a return mnemonic.                                                                                                     | Must combine with umask 80H        |

**Table A-2. Non-Architectural Performance Events In the Processor Core for Intel Core i7, i5, i3 Processors 2xxx Series**

| Event Num. | Umask Value | Event Mask Mnemonic                    | Description                                                                                            | Comment                          |
|------------|-------------|----------------------------------------|--------------------------------------------------------------------------------------------------------|----------------------------------|
| 88H        | 10H         | BR_INST_EXEC.DIRECT_NEAR_CALL          | Qualify unconditional near call branch instructions, excluding non call branch, executed.              | Must combine with umask 80H      |
| 88H        | 20H         | BR_INST_EXEC.INDIRECT_NEAR_CALL        | Qualify indirect near calls, including both register and memory indirect, executed.                    | Must combine with umask 80H      |
| 88H        | 40H         | BR_INST_EXEC.NON_TAKEN                 | Qualify non-taken near branches executed.                                                              | Applicable to umask 01H only     |
| 88H        | 80H         | BR_INST_EXEC.TAKEN                     | Qualify taken near branches executed. Must combine with 01H,02H, 04H, 08H, 10H, 20H                    |                                  |
| 88H        | FFH         | BR_INST_EXEC.ALL_BRANCHES              | Counts all near executed branches (not necessarily retired).                                           |                                  |
| 89H        | 01H         | BR_MISP_EXEC.COND                      | Qualify conditional near branch instructions mispredicted.                                             | Must combine with umask 40H, 80H |
| 89H        | 04H         | BR_MISP_EXEC.INDIRECT_JMP_NON_CALL_RET | Qualify mispredicted indirect near branch instructions that are not calls nor returns.                 | Must combine with umask 80H      |
| 89H        | 08H         | BR_MISP_EXEC.RETURN_NEAR               | Qualify mispredicted indirect near branches that have a return mnemonic.                               | Must combine with umask 80H      |
| 89H        | 10H         | BR_MISP_EXEC.DIRECT_NEAR_CALL          | Qualify mispredicted unconditional near call branch instructions, excluding non call branch, executed. | Must combine with umask 80H      |
| 89H        | 20H         | BR_MISP_EXEC.INDIRECT_NEAR_CALL        | Qualify mispredicted indirect near calls, including both register and memory indirect, executed.       | Must combine with umask 80H      |
| 89H        | 40H         | BR_MISP_EXEC.NON_TAKEN                 | Qualify mispredicted non-taken near branches executed.                                                 | Applicable to umask 01H only     |
| 89H        | 80H         | BR_MISP_EXEC.TAKEN                     | Qualify mispredicted taken near branches executed. Must combine with 01H,02H, 04H, 08H, 10H, 20H       |                                  |
| 89H        | FFH         | BR_MISP_EXEC.ALL_BRANCHES              | Counts all near executed branches (not necessarily retired).                                           |                                  |
| 9CH        | 01H         | IDQ_UOPS_NOT_DELIVERED.CORE            | Count number of non-delivered uops to RAT per thread.                                                  | Use Cmask to qualify uop b/w     |

## PERFORMANCE-MONITORING EVENTS

**Table A-2. Non-Architectural Performance Events In the Processor Core for Intel Core i7, i5, i3 Processors 2xxx Series**

| Event Num. | Umask Value | Event Mask Mnemonic             | Description                                                                                    | Comment |
|------------|-------------|---------------------------------|------------------------------------------------------------------------------------------------|---------|
| A1H        | 01H         | UOPS_DISPATCHED_PORT.PORT_0     | Cycles which a Uop is dispatched on port 0.                                                    |         |
| A1H        | 02H         | UOPS_DISPATCHED_PORT.PORT_1     | Cycles which a Uop is dispatched on port 1.                                                    |         |
| A1H        | 04H         | UOPS_DISPATCHED_PORT.PORT_2_LD  | Cycles which a load uop is dispatched on port 2.                                               |         |
| A1H        | 08H         | UOPS_DISPATCHED_PORT.PORT_2_STA | Cycles which a store address uop is dispatched on port 2.                                      |         |
| A1H        | 0CH         | UOPS_DISPATCHED_PORT.PORT_2     | Cycles which a Uop is dispatched on port 2.                                                    |         |
| A1H        | 10H         | UOPS_DISPATCHED_PORT.PORT_3_LD  | Cycles which a load uop is dispatched on port 3.                                               |         |
| A1H        | 20H         | UOPS_DISPATCHED_PORT.PORT_3_STA | Cycles which a store address uop is dispatched on port 3.                                      |         |
| A1H        | 30H         | UOPS_DISPATCHED_PORT.PORT_3     | Cycles which a Uop is dispatched on port 3.                                                    |         |
| A1H        | 40H         | UOPS_DISPATCHED_PORT.PORT_4     | Cycles which a Uop is dispatched on port 4.                                                    |         |
| A1H        | 80H         | UOPS_DISPATCHED_PORT.PORT_5     | Cycles which a Uop is dispatched on port 5.                                                    |         |
| A2H        | 01H         | RESOURCE_STALLS.ANY             | Cycles Allocation is stalled due to Resource Related reason.                                   |         |
| A2H        | 02H         | RESOURCE_STALLS.LB              | Counts the cycles of stall due to lack of load buffers.                                        |         |
| A2H        | 04H         | RESOURCE_STALLS.RS              | Cycles stalled due to no eligible RS entry available.                                          |         |
| A2H        | 08H         | RESOURCE_STALLS.SB              | Cycles stalled due to no store buffers available. (not including draining from sync).          |         |
| A2H        | 10H         | RESOURCE_STALLS.ROB             | Cycles stalled due to re-order buffer full.                                                    |         |
| A2H        | 20H         | RESOURCE_STALLS.FCSW            | Cycles stalled due to writing the FPU control word.                                            |         |
| A2H        | 40H         | RESOURCE_STALLS.MXCSR           | Cycles stalled due to the MXCSR register rename occurring to close to a previous MXCSR rename. |         |

**Table A-2. Non-Architectural Performance Events In the Processor Core for Intel Core i7, i5, i3 Processors 2xxx Series**

| Event Num. | Umask Value | Event Mask Mnemonic               | Description                                                                                                                                                                                                                                                     | Comment                |
|------------|-------------|-----------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------|
| A2H        | 80H         | RESOURCE_STALLS. OTHER            | Cycles stalled while execution was stalled due to other resource issues.                                                                                                                                                                                        |                        |

| B1H        | 01H         | UOPS_DISPATCHED.T HREAD           | Counts total number of uops to be dispatched per-thread each cycle. Set Cmask = 1, INV = 1 to count stall cycles.                                                                                                                                               |                        |
| B1H        | 02H         | UOPS_DISPATCHED.C ORE             | Counts total number of uops to be dispatched per-core each cycle.                                                                                                                                                                                               | Do not need to set ANY |
| B2H        | 01H         | OFFCORE_REQUEST S_BUFFER.SQ_FULL  | Offcore requests buffer cannot take more entries for this thread core.                                                                                                                                                                                          |                        |
| B6H        | 01H         | AGU_BYPASS_CANCE L.COUNT          | Counts executed load operations with all the following traits: 1. addressing of the format [base + offset], 2. the offset is between 1 and 2047, 3. the address specified in the base register is in one page and the address [base+offset] is in another page. |                        |

## PERFORMANCE-MONITORING EVENTS

**Table A-2. Non-Architectural Performance Events In the Processor Core for Intel Core i7, i5, i3 Processors 2xxx Series**

| Event Num. | Umask Value | Event Mask Mnemonic                | Description                                                                                              | Comment                             |
|------------|-------------|------------------------------------|----------------------------------------------------------------------------------------------------------|-------------------------------------|
| B7H        | 01H         | OFF_CORE_RESPONS_E_0               | see Section 30.8.5, "Off-core Response Performance Monitoring"; PMCO only.                               | Requires programming MSR 01A6H      |
| BBH        | 01H         | OFF_CORE_RESPONS_E_1               | See Section 30.8.5, "Off-core Response Performance Monitoring". PMC3 only.                               | Requires programming MSR 01A7H      |
| BDH        | 01H         | TLB_FLUSH.DTLB_T_HREAD             | DTLB flush attempts of the thread-specific entries                                                       |                                     |
| BDH        | 20H         | TLB_FLUSH.STLB_A_NY                | Count number of STLB flush attempts                                                                      |                                     |
| BFH        | 05H         | L1D_BLOCKS.BANK_CONFLICT_CYCLES    | Cycles when dispatched loads are cancelled due to L1D bank conflicts with other load ports               | cmask=1                             |
| COH        | 00H         | INST_RETIREDA.NY_P                 | Number of instructions at retirement                                                                     | See Table A-1                       |
| COH        | 01H         | INST_RETIREDA.PREC_DIST            | Precise instruction retired event with HW to reduce effect of PEBS shadow in IP distribution             | PMC1 only; Must quiesce other PMCs. |
| COH        | 02H         | INST_RETIREDX87                    | X87 instruction retired event                                                                            |                                     |
| C1H        | 02H         | OTHER_ASSISTS.ITAL_B_MISS_RETIREDA | Instructions that experienced an ITLB miss.                                                              |                                     |
| C1H        | 08H         | OTHER_ASSISTS.AVX_STORE            | Number of assists associated with 256-bit AVX store operations.                                          |                                     |
| C1H        | 10H         | OTHER_ASSISTS.AVX_TO_SSE           | Number of transitions from AVX-256 to legacy SSE when penalty applicable.                                |                                     |
| C1H        | 20H         | OTHER_ASSISTS.SSE_TO_AVX           | Number of transitions from SSE to AVX-256 when penalty applicable.                                       |                                     |
| C2H        | 01H         | UOPS_RETIREDA.ALL                  | Counts the number of micro-ops retired, Use cmask=1 and invert to count active cycles or stalled cycles. | Supports PEBS                       |
| C2H        | 02H         | UOPS_RETIREDA.RE_SLOTS             | Counts the number of retirement slots used each cycle.                                                   |                                     |
| C3H        | 02H         | MACHINE_CLEARSMEMORY_ORDERING      | Counts the number of machine clears due to memory order conflicts.                                       |                                     |

**Table A-2. Non-Architectural Performance Events In the Processor Core for Intel Core i7, i5, i3 Processors 2xxx Series**

| Event Num. | Umask Value | Event Mask Mnemonic         | Description                                                                                                                  | Comment       |
|------------|-------------|-----------------------------|------------------------------------------------------------------------------------------------------------------------------|---------------|
| C3H        | 04H         | MACHINE_CLEARSS.MC          | Counts the number of times that a program writes to a code section.                                                          |               |
| C3H        | 20H         | MACHINE_CLEARSMASKMOV       | Counts the number of executed AVX masked load operations that refer to an illegal address range with the mask bits set to 0. |               |
| C4H        | 00H         | BR_INST_RETIRED.AL_BRANCHES | Branch instructions at retirement                                                                                            | See Table A-1 |
| C4H        | 01H         | BR_INST_RETIRED.CONDITIONAL | Counts the number of conditional branch instructions retired.                                                                | Supports PEBS |
| C4H        | 02H         | BR_INST_RETIRED.NEAR_CALL   | Direct and indirect near call instructions retired.                                                                          |               |
| C4H        | 04H         | BR_INST_RETIRED.AL_BRANCHES | Counts the number of branch instructions retired.                                                                            |               |
| C4H        | 08H         | BR_INST_RETIRED.NEAR_RETURN | Counts the number of near return instructions retired.                                                                       |               |
| C4H        | 10H         | BR_INST_RETIRED.NOT_TAKEN   | Counts the number of not taken branch instructions retired.                                                                  |               |
| C4H        | 20H         | BR_INST_RETIRED.NEAR_TAKEN  | Number of near taken branches retired.                                                                                       |               |
| C4H        | 40H         | BR_INST_RETIRED.FAR_BRANCH  | Number of far branches retired.                                                                                              |               |
| C5H        | 00H         | BR_MISP_RETIRED.AL_BRANCHES | Mispredicted branch instructions at retirement                                                                               | See Table A-1 |
| C5H        | 01H         | BR_MISP_RETIRED.CONDITIONAL | Mispredicted conditional branch instructions retired.                                                                        | Supports PEBS |
| C5H        | 02H         | BR_MISP_RETIRED.NEAR_CALL   | Direct and indirect mispredicted near call instructions retired.                                                             |               |
| C5H        | 04H         | BR_MISP_RETIRED.AL_BRANCHES | Mispredicted macro branch instructions retired.                                                                              |               |
| C5H        | 10H         | BR_MISP_RETIRED.NOT_TAKEN   | Mispredicted not taken branch instructions retired.                                                                          |               |
| C5H        | 20H         | BR_MISP_RETIRED.TAKEN       | Mispredicted taken branch instructions retired.                                                                              |               |
| CAH        | 02H         | FP_ASSIST.X87_OUTPUT        | Number of X87 assists due to output value.                                                                                   |               |

## PERFORMANCE-MONITORING EVENTS

**Table A-2. Non-Architectural Performance Events In the Processor Core for Intel Core i7, i5, i3 Processors 2xxx Series**

| Event Num. | Umask Value | Event Mask Mnemonic              | Description                                                                                       | Comment                        |
|------------|-------------|----------------------------------|---------------------------------------------------------------------------------------------------|--------------------------------|
| CAH        | 04H         | FP_ASSIST.X87_INP_UT             | Number of X87 assists due to input value.                                                         |                                |
| CAH        | 08H         | FP_ASSIST SIMD_OU_TPUT           | Number of SIMD FP assists due to Output values                                                    |                                |
| CAH        | 10H         | FP_ASSIST SIMD_INP_UT            | Number of SIMD FP assists due to input values                                                     |                                |
| CAH        | 1EH         | FP_ASSIST.ANY                    | Cycles with any input/output SSE* or FP assists                                                   |                                |
| CCH        | 20H         | ROB_MISC_EVENTS.L_BR_INSERTS     | Count cases of saving new LBR records by hardware.                                                |                                |
| CDH        | 01H         | MEM_TRANS_RETIR ED.LOAD_LATENCY  | Sample loads with specified latency threshold. PMC3 only.                                         | Specify threshold in MSR 0x3F6 |
| CDH        | 02H         | MEM_TRANS_RETIR ED.PRECISE_STORE | Sample stores and collect precise store operation via PEBS record. PMC3 only.                     | See Section 30.8.4.3           |
| DOH        | 01H         | MEM_UOP_RETIREDF LOADS           | Qualify retired memory uops that are loads. Combine with umask 10H, 20H, 40H, 80H.                | Supports PEBS                  |
| DOH        | 02H         | MEM_UOP_RETIREDF STORES          | Qualify retired memory uops that are stores. Combine with umask 10H, 20H, 40H, 80H.               |                                |
| DOH        | 10H         | MEM_UOP_RETIREDF STLB_MISS       | Qualify retired memory uops with STLB miss. Must combine with umask 01H, 02H, to produce counts.  |                                |
| DOH        | 20H         | MEM_UOP_RETIREDF LOCK            | Qualify retired memory uops with lock. Must combine with umask 01H, 02H, to produce counts.       |                                |
| DOH        | 40H         | MEM_UOP_RETIREDF SPLIT           | Qualify retired memory uops with line split. Must combine with umask 01H, 02H, to produce counts. |                                |
| DOH        | 80H         | MEM_UOP_RETIREDF ALL             | Qualify any retired memory uops. Must combine with umask 01H, 02H, to produce counts.             |                                |
| D1H        | 01H         | MEM_LOAD_UOPS_R ETIRED.L1_HIT    | Retired load uops with L1 cache hits as data sources.                                             | Supports PEBS                  |
| D1H        | 02H         | MEM_LOAD_UOPS_R ETIRED.L2_HIT    | Retired load uops with L2 cache hits as data sources.                                             |                                |

## PERFORMANCE-MONITORING EVENTS

**Table A-2. Non-Architectural Performance Events In the Processor Core for Intel Core i7, i5, i3 Processors 2xxx Series**

| Event Num. | Umask Value | Event Mask Mnemonic                        | Description                                                                                                                                | Comment        |
|------------|-------------|--------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------|----------------|
| D1H        | 04H         | MEM_LOAD_UOPS_R ETIRED.LLC_HIT             | Retired load uops which data sources were data hits in LLC without snoops required.                                                        |                |
| D1H        | 40H         | MEM_LOAD_UOPS_R ETIRED.HIT_LFB             | Retired load uops which data sources were load uops missed L1 but hit FB due to preceding miss to the same cache line with data not ready. |                |
| D2H        | 01H         | MEM_LOAD_UOPS_L LC_HIT_RETIREDS.XS NP_MISS | Retired load uops which data sources were LLC hit and cross-core snoop missed in on-pkg core cache.                                        | Supports PEBS  |
| D2H        | 02H         | MEM_LOAD_UOPS_L LC_HIT_RETIREDS.XS NP_HIT  | Retired load uops which data sources were LLC and cross-core snoop hits in on-pkg core cache.                                              |                |
| D2H        | 04H         | MEM_LOAD_UOPS_L LC_HIT_RETIREDS.XS NP_HITM | Retired load uops which data sources were HitM responses from shared LLC.                                                                  |                |
| D2H        | 08H         | MEM_LOAD_UOPS_L LC_HIT_RETIREDS.XS NP_NONE | Retired load uops which data sources were hits in LLC without snoops required.                                                             |                |
| D4H        | 02H         | MEM_LOAD_UOPS_M ISC_RETIREDS.LLC_MISS      | Retired load uops with unknown information as data source in cache serviced the load.                                                      | Supports PEBS. |
| FOH        | 01H         | L2_TRANS.DEMAND_DATA_RD                    | Demand Data Read requests that access L2 cache                                                                                             |                |
| FOH        | 02H         | L2_TRANS.RFO                               | RFO requests that access L2 cache                                                                                                          |                |
| FOH        | 04H         | L2_TRANS.CODE_RD                           | L2 cache accesses when fetching instructions                                                                                               |                |
| FOH        | 08H         | L2_TRANS.ALL_PF                            | L2 or LLC HW prefetches that access L2 cache including rejects.                                                                            |                |
| FOH        | 10H         | L2_TRANS.L1D_WB                            | L1D writebacks that access L2 cache                                                                                                        |                |
| FOH        | 20H         | L2_TRANS.L2_FILL                           | L2 fill requests that access L2 cache                                                                                                      |                |
| FOH        | 40H         | L2_TRANS.L2_WB                             | L2 writebacks that access L2 cache                                                                                                         |                |
| FOH        | 80H         | L2_TRANS.ALL_REQUESTS                      | Transactions accessing L2 pipe                                                                                                             |                |

## PERFORMANCE-MONITORING EVENTS

**Table A-2. Non-Architectural Performance Events In the Processor Core for Intel Core i7, i5, i3 Processors 2xxx Series**

| Event Num. | Umask Value | Event Mask Mnemonic       | Description                                 | Comment                          |
|------------|-------------|---------------------------|---------------------------------------------|----------------------------------|
| F1H        | 01H         | L2_LINES_IN.I             | L2 cache lines in I state filling L2        | Counting does not cover rejects. |
| F1H        | 02H         | L2_LINES_IN.S             | L2 cache lines in S state filling L2        | Counting does not cover rejects. |
| F1H        | 04H         | L2_LINES_IN.E             | L2 cache lines in E state filling L2        | Counting does not cover rejects. |
| F1H        | 07H         | L2_LINES_IN.ALL           | L2 cache lines filling L2                   | Counting does not cover rejects. |
| F2H        | 01H         | L2_LINES_OUT.DEMAND_CLEAN | Clean L2 cache lines evicted by demand      |                                  |
| F2H        | 02H         | L2_LINES_OUT.DEMAND_DIRTY | Dirty L2 cache lines evicted by demand      |                                  |
| F2H        | 04H         | L2_LINES_OUT.PF_CLEAN     | Clean L2 cache lines evicted by L2 prefetch |                                  |
| F2H        | 08H         | L2_LINES_OUT.PF_DIRTY     | Dirty L2 cache lines evicted by L2 prefetch |                                  |
| F2H        | 0AH         | L2_LINES_OUT.DIRTY_ALL    | Dirty L2 cache lines filling the L2         | Counting does not cover rejects. |
| F4H        | 10H         | SQ_MISC.SPLIT_LOCK        | Split locks in SQ                           |                                  |

Non-architectural Performance monitoring events that are located in the uncore sub-system are implementation specific between different platforms using processors based on Intel microarchitecture Sandy Bridge. Processors with CPUID signature of DisplayFamily\_DisplayModel 06\_2AH support performance events listed in Table A-3.

**Table A-3. Non-Architectural Performance Events In the Processor Uncore for Intel Core i7, i5, i3 Processor 2xxx Series**

| Event Num. | Umask Value | Event Mask Mnemonic                | Description                                                                                                               | Comment                                                         |
|------------|-------------|------------------------------------|---------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------|
| 22H        | 01H         | UNC_CBO_XSNP_RESPONSE.RSPIHITI     | Snoop responses received from processor cores to requests initiated by this Cbox.                                         | Must combine with one of the umask values of 20H, 40H, 80H      |
| 22H        | 02H         | UNC_CBO_XSNP_RESPONSE.RSPIHITFSE   |                                                                                                                           |                                                                 |
| 22H        | 04H         | UNC_CBO_XSNP_RESPONSE.RSPSHITFSE   |                                                                                                                           |                                                                 |
| 22H        | 08H         | UNC_CBO_XSNP_RESPONSE.RSPSFWDM     |                                                                                                                           |                                                                 |
| 22H        | 01H         | UNC_CBO_XSNP_RESPONSE.RSPIFWDM     |                                                                                                                           |                                                                 |
| 22H        | 20H         | UNC_CBO_XSNP_RESPONSE.AND_EXTERNAL | Filter on cross-core snoops resulted in external snoop request. Must combine with at least one of 01H, 02H, 04H, 08H, 10H |                                                                 |
| 22H        | 40H         | UNC_CBO_XSNP_RESPONSE.AND_XCORE    | Filter on cross-core snoops resulted in core request. Must combine with at least one of 01H, 02H, 04H, 08H, 10H           |                                                                 |
| 22H        | 80H         | UNC_CBO_XSNP_RESPONSE.AND_XCORE    | Filter on cross-core snoops resulted in LLC evictions. Must combine with at least one of 01H, 02H, 04H, 08H, 10H          |                                                                 |
| 34H        | 01H         | UNC_CBO_CACHE_LO_OKUP.M            | LLC lookup request that access cache and found line in M-state.                                                           | Must combine with one of the umask values of 10H, 20H, 40H, 80H |
| 34H        | 02H         | UNC_CBO_CACHE_LO_OKUP.E            | LLC lookup request that access cache and found line in E-state.                                                           |                                                                 |
| 34H        | 04H         | UNC_CBO_CACHE_LO_OKUP.S            | LLC lookup request that access cache and found line in S-state.                                                           |                                                                 |
| 34H        | 08H         | UNC_CBO_CACHE_LO_OKUP.I            | LLC lookup request that access cache and found line in I-state.                                                           |                                                                 |
| 34H        | 10H         | UNC_CBO_CACHE_LO_OKUP.AND_READ     | Filter on processor core initiated cacheable read requests. Must combine with at least one of 01H, 02H, 04H, 08H          |                                                                 |
| 34H        | 20H         | UNC_CBO_CACHE_LO_OKUP.AND_READ     | Filter on processor core initiated cacheable write requests. Must combine with at least one of 01H, 02H, 04H, 08H         |                                                                 |

## PERFORMANCE-MONITORING EVENTS

**Table A-3. Non-Architectural Performance Events In the Processor Uncore for Intel Core i7, i5, i3 Processor 2xxx Series**

| Event Num. | Umask Value | Event Mask Mnemonic                  | Description                                                                                                                                                                                    | Comment        |
|------------|-------------|--------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------|
| 34H        | 40H         | UNC_CBO_CACHE_LO_OKUP.AND_EXT SNP    | Filter on external snoop requests. Must combine with at least one of 01H, 02H, 04H, 08H                                                                                                        |                |
| 34H        | 80H         | UNC_CBO_CACHE_LO_OKUP.AND_ANY        | Filter on any IRQ or IPQ initiated requests including uncacheable, non-coherent requests. Must combine with at least one of 01H, 02H, 04H, 08H                                                 |                |
| 80H        | 01H         | UNC_IMPH_CBO_TRK _OCCUPANCY.ALL      | Counts cycles weighted by the number of core-outgoing valid entries. Valid entries are between allocation to the first of IDIO or DRSO messages. Accounts for coherent and in-coherent traffic | Counter 0 only |
| 81H        | 01H         | UNC_IMPH_CBO_TRK _REQUEST.ALL        | Counts the number of core-outgoing entries. Accounts for coherent and in-coherent traffic                                                                                                      |                |
| 81H        | 20H         | UNC_IMPH_CBO_TRK _REQUEST.WRITES     | Counts the number of allocated write entries, include full, partial, and evictions.                                                                                                            |                |
| 81H        | 80H         | UNC_IMPH_CBO_TRK _REQUEST.EVICTION S | Counts the number of evictions allocated.                                                                                                                                                      |                |
| 83H        | 01H         | UNC_IMPH_COH_TR K_OCCUPANCY.ALL      | Counts cycles weighted by the number of core-outgoing valid entries in the coherent tracker queue.                                                                                             | Counter 0 only |
| 84H        | 01H         | UNC_IMPH_COH_TR K_REQUEST.ALL        | Counts the number of core-outgoing entries in the coherent tracker queue.                                                                                                                      |                |

## A.3 PERFORMANCE MONITORING EVENTS FOR INTEL® CORE™ i7 PROCESSOR FAMILY AND XEON PROCESSOR FAMILY

Processors based on the Intel microarchitecture code name Nehalem support the architectural and non-architectural performance-monitoring events listed in Table A-1 and Table A-4. The events in Table A-4 generally applies to processors with

## PERFORMANCE-MONITORING EVENTS

CPUID signature of DisplayFamily\_DisplayModel encoding with the following values: 06\_1AH, 06\_1EH, 06\_1FH, and 06\_2EH. However, Intel Xeon processors with CPUID signature of DisplayFamily\_DisplayModel 06\_2EH have a small number of events that are not supported in processors with CPUID signature 06\_1AH, 06\_1EH, and 06\_1FH. These events are noted in the comment column.

In addition, these processors (CPUID signature of DisplayFamily\_DisplayModel 06\_1AH, 06\_1EH, 06\_1FH) also support the following non-architectural, product-specific uncore performance-monitoring events listed in Table A-5.

Fixed counters in the core PMU support the architecture events defined in Table A-9.

**Table A-4. Non-Architectural Performance Events In the Processor Core for Intel Core i7 Processor and Intel Xeon Processor 5500 Series**

| Event Num. | Umask Value | Event Mask Mnemonic              | Description                                                                                                                                                                                                                                                                                                                                           | Comment |
|------------|-------------|----------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------|
| 04H        | 07H         | SB_DRAIN.ANY                     | Counts the number of store buffer drains.                                                                                                                                                                                                                                                                                                             |         |
| 06H        | 04H         | STORE_BLOCKS.AT_RET              | Counts number of loads delayed with at-Retirement block code. The following loads need to be executed at retirement and wait for all senior stores on the same thread to be drained: load splitting across 4K boundary (page split), load accessing uncacheable (UC or USWC) memory, load lock, and load with page table in UC or USWC memory region. |         |
| 06H        | 08H         | STORE_BLOCKS.L1D_BLOCK           | Cacheable loads delayed with L1D block code.                                                                                                                                                                                                                                                                                                          |         |
| 07H        | 01H         | PARTIAL_ADDRESS_ALIAS            | Counts false dependency due to partial address aliasing.                                                                                                                                                                                                                                                                                              |         |
| 08H        | 01H         | DTLB_LOAD_MISSES. ANY            | Counts all load misses that cause a page walk.                                                                                                                                                                                                                                                                                                        |         |
| 08H        | 02H         | DTLB_LOAD_MISSES. WALK_COMPLETED | Counts number of completed page walks due to load miss in the STLB.                                                                                                                                                                                                                                                                                   |         |
| 08H        | 10H         | DTLB_LOAD_MISSES. STLB_HIT       | Number of cache load STLB hits.                                                                                                                                                                                                                                                                                                                       |         |
| 08H        | 20H         | DTLB_LOAD_MISSES. PDE_MISS       | Number of DTLB cache load misses where the low part of the linear to physical address translation was missed.                                                                                                                                                                                                                                         |         |

## PERFORMANCE-MONITORING EVENTS

**Table A-4. Non-Architectural Performance Events In the Processor Core for Intel Core i7 Processor and Intel Xeon Processor 5500 Series**

| Event Num. | Umask Value | Event Mask Mnemonic                      | Description                                                                                                                                                                                                               | Comment                                   |
|------------|-------------|------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------|
| 08H        | 80H         | DTLB_LOAD_MISSES.LARGE_WALK_COMPLETED    | Counts number of completed large page walks due to load miss in the STLB.                                                                                                                                                 |                                           |
| 0BH        | 01H         | MEM_INST_RETIRED.LOADS                   | Counts the number of instructions with an architecturally-visible load retired on the architected path.                                                                                                                   |                                           |
| 0BH        | 02H         | MEM_INST_RETIRED.STORES                  | Counts the number of instructions with an architecturally-visible store retired on the architected path.                                                                                                                  |                                           |
| 0BH        | 10H         | MEM_INST_RETIRED.LATENCY_ABOVE_THRESHOLD | Counts the number of instructions exceeding the latency specified with ld_lat facility.                                                                                                                                   | In conjunction with ld_lat facility       |
| 0CH        | 01H         | MEM_STORE_RETIRED.DTLB_MISS              | The event counts the number of retired stores that missed the DTLB. The DTLB miss is not counted if the store operation causes a fault. Does not counter prefetches. Counts both primary and secondary misses to the TLB. |                                           |
| 0EH        | 01H         | UOPS_ISSUED.ANY                          | Counts the number of Uops issued by the Register Allocation Table to the Reservation Station, i.e. the UOPs issued from the front end to the back end.                                                                    |                                           |
| 0EH        | 01H         | UOPS_ISSUEDSTALL_ED_CYCLES               | Counts the number of cycles no Uops issued by the Register Allocation Table to the Reservation Station, i.e. the UOPs issued from the front end to the back end.                                                          | set "invert=1, cmask = 1"                 |
| 0EH        | 02H         | UOPS_ISSUED.FUSED                        | Counts the number of fused Uops that were issued from the Register Allocation Table to the Reservation Station.                                                                                                           |                                           |
| 0FH        | 01H         | MEM_UNCORE_RETIRED.L3_DATA_MISS_UNKNOWN  | Counts number of memory load instructions retired where the memory reference missed L3 and data source is unknown.                                                                                                        | Available only for CPUID signature 06_2EH |

**Table A-4. Non-Architectural Performance Events In the Processor Core for Intel Core i7 Processor and Intel Xeon Processor 5500 Series**

| Event Num. | Umask Value | Event Mask Mnemonic                            | Description                                                                                                                                                                                                                                                                               | Comment                                   |
|------------|-------------|------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------|
| OFH        | 02H         | MEM_UNCORE_RETIRED.OTHER_CORE_L2_HITM          | Counts number of memory load instructions retired where the memory reference hit modified data in a sibling core residing on the same socket.                                                                                                                                             |                                           |
| OFH        | 08H         | MEM_UNCORE_RETIRED.REMOTE_CACHE_LOCAL_HOME_HIT | Counts number of memory load instructions retired where the memory reference missed the L1, L2 and L3 caches and HIT in a remote socket's cache. Only counts locally homed lines.                                                                                                         |                                           |
| OFH        | 10H         | MEM_UNCORE_RETIRED.REMOTE_DRAM                 | Counts number of memory load instructions retired where the memory reference missed the L1, L2 and L3 caches and was remotely homed. This includes both DRAM access and HITM in a remote socket's cache for remotely homed lines.                                                         |                                           |
| OFH        | 20H         | MEM_UNCORE_RETIRED.LOCAL_DRAM                  | Counts number of memory load instructions retired where the memory reference missed the L1, L2 and L3 caches and required a local socket memory reference. This includes locally homed cachelines that were in a modified state in another socket.                                        |                                           |
| OFH        | 80H         | MEM_UNCORE_RETIRED.UNCACHEABLE                 | Counts number of memory load instructions retired where the memory reference missed the L1, L2 and L3 caches and to perform I/O.                                                                                                                                                          | Available only for CPUID signature 06_2EH |
| 10H        | 01H         | FP_COMP_OPS_EXE_X87                            | Counts the number of FP Computational Uops Executed. The number of FADD, FSUB, FCOM, FMULs, integer MULs and IMULs, FDIVs, FPREMs, FSQRTs, integer DIVs, and IDIVs. This event does not distinguish an FADD used in the middle of a transcendental flow from a separate FADD instruction. |                                           |

## PERFORMANCE-MONITORING EVENTS

**Table A-4. Non-Architectural Performance Events In the Processor Core for Intel Core i7 Processor and Intel Xeon Processor 5500 Series**

| Event Num. | Umask Value | Event Mask Mnemonic                  | Description                                                                                         | Comment |
|------------|-------------|--------------------------------------|-----------------------------------------------------------------------------------------------------|---------|
| 10H        | 02H         | FP_COMP_OPS_EXE_MMX                  | Counts number of MMX Uops executed.                                                                 |         |
| 10H        | 04H         | FP_COMP_OPS_EXE_SSE_FP               | Counts number of SSE and SSE2 FP uops executed.                                                     |         |
| 10H        | 08H         | FP_COMP_OPS_EXE_SSE2_INTEGER         | Counts number of SSE2 integer uops executed.                                                        |         |
| 10H        | 10H         | FP_COMP_OPS_EXE_SSE_FP_PACKED        | Counts number of SSE FP packed uops executed.                                                       |         |
| 10H        | 20H         | FP_COMP_OPS_EXE_SSE_FP_SCALAR        | Counts number of SSE FP scalar uops executed.                                                       |         |
| 10H        | 40H         | FP_COMP_OPS_EXE_SSE_SINGLE_PRECISION | Counts number of SSE* FP single precision uops executed.                                            |         |
| 10H        | 80H         | FP_COMP_OPS_EXE_SSE_DOUBLE_PRECISION | Counts number of SSE* FP double precision uops executed.                                            |         |
| 12H        | 01H         | SIMD_INT_128.PACKED_MPY              | Counts number of 128 bit SIMD integer multiply operations.                                          |         |
| 12H        | 02H         | SIMD_INT_128.PACKED_SHIFT            | Counts number of 128 bit SIMD integer shift operations.                                             |         |
| 12H        | 04H         | SIMD_INT_128.PACK                    | Counts number of 128 bit SIMD integer pack operations.                                              |         |
| 12H        | 08H         | SIMD_INT_128.UNPACK                  | Counts number of 128 bit SIMD integer unpack operations.                                            |         |
| 12H        | 10H         | SIMD_INT_128.PACKED_LOGICAL          | Counts number of 128 bit SIMD integer logical operations.                                           |         |
| 12H        | 20H         | SIMD_INT_128.PACKED_ARITH            | Counts number of 128 bit SIMD integer arithmetic operations.                                        |         |
| 12H        | 40H         | SIMD_INT_128.SHUFFLE_MOVE            | Counts number of 128 bit SIMD integer shuffle and move operations.                                  |         |
| 13H        | 01H         | LOAD_DISPATCH.RS                     | Counts number of loads dispatched from the Reservation Station that bypass the Memory Order Buffer. |         |

**Table A-4. Non-Architectural Performance Events In the Processor Core for Intel Core i7 Processor and Intel Xeon Processor 5500 Series**

| Event Num. | Umask Value | Event Mask Mnemonic      | Description                                                                                                                                                                                                                                                                            | Comment                                |
|------------|-------------|--------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------|
| 13H        | 02H         | LOAD_DISPATCH.RS_DELAYED | Counts the number of delayed RS dispatches at the stage latch. If an RS dispatch can not bypass to LB, it has another chance to dispatch from the one-cycle delayed staging latch before it is written into the LB.                                                                    |                                        |
| 13H        | 04H         | LOAD_DISPATCH.MOB        | Counts the number of loads dispatched from the Reservation Station to the Memory Order Buffer.                                                                                                                                                                                         |                                        |
| 13H        | 07H         | LOAD_DISPATCH.ANY        | Counts all loads dispatched from the Reservation Station.                                                                                                                                                                                                                              |                                        |
| 14H        | 01H         | ARITH.CYCLES_DIV_BUSY    | Counts the number of cycles the divider is busy executing divide or square root operations. The divide can be integer, X87 or Streaming SIMD Extensions (SSE). The square root operation can be either X87 or SSE.<br>Set 'edge =1, invert=1, cmask=1' to count the number of divides. | Count may be incorrect When SMT is on. |
| 14H        | 02H         | ARITH.MUL                | Counts the number of multiply operations executed. This includes integer as well as floating point multiply operations but excludes DPPS mul and MPSAD.                                                                                                                                | Count may be incorrect When SMT is on  |
| 17H        | 01H         | INST_QUEUE_WRITE_S       | Counts the number of instructions written into the instruction queue every cycle.                                                                                                                                                                                                      |                                        |
| 18H        | 01H         | INST_DECODED.DECO        | Counts number of instructions that require decoder 0 to be decoded. Usually, this means that the instruction maps to more than 1 uop.                                                                                                                                                  |                                        |
| 19H        | 01H         | TWO_UOP_INSTS_DECODED    | An instruction that generates two uops was decoded.                                                                                                                                                                                                                                    |                                        |

## PERFORMANCE-MONITORING EVENTS

**Table A-4. Non-Architectural Performance Events In the Processor Core for Intel Core i7 Processor and Intel Xeon Processor 5500 Series**

| Event Num. | Umask Value | Event Mask Mnemonic      | Description                                                                                                                                                                                                                                                                                                                                                                                                                                            | Comment                                                                                                                                      |
|------------|-------------|--------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------|
| 1EH        | 01H         | INST_QUEUE_WRITE _CYCLES | This event counts the number of cycles during which instructions are written to the instruction queue. Dividing this counter by the number of instructions written to the instruction queue (INST_QUEUE_Writes) yields the average number of instructions decoded each cycle. If this number is less than four and the pipe stalls, this indicates that the decoder is failing to decode enough instructions per cycle to sustain the 4-wide pipeline. | If SSE* instructions that are 6 bytes or longer arrive one after another, then front end throughput may limit execution speed. In such case, |
| 20H        | 01H         | LSD_OVERFLOW             | Counts number of loops that can't stream from the instruction queue.                                                                                                                                                                                                                                                                                                                                                                                   |                                                                                                                                              |
| 24H        | 01H         | L2_RQSTS.LD_HIT          | Counts number of loads that hit the L2 cache. L2 loads include both L1D demand misses as well as L1D prefetches. L2 loads can be rejected for various reasons. Only non rejected loads are counted.                                                                                                                                                                                                                                                    |                                                                                                                                              |
| 24H        | 02H         | L2_RQSTS.LD_MISS         | Counts the number of loads that miss the L2 cache. L2 loads include both L1D demand misses as well as L1D prefetches.                                                                                                                                                                                                                                                                                                                                  |                                                                                                                                              |
| 24H        | 03H         | L2_RQSTS.LLOADS          | Counts all L2 load requests. L2 loads include both L1D demand misses as well as L1D prefetches.                                                                                                                                                                                                                                                                                                                                                        |                                                                                                                                              |
| 24H        | 04H         | L2_RQSTS.RFO_HIT         | Counts the number of store RFO requests that hit the L2 cache. L2 RFO requests include both L1D demand RFO misses as well as L1D RFO prefetches. Count includes WC memory requests, where the data is not fetched but the permission to write the line is required.                                                                                                                                                                                    |                                                                                                                                              |

**Table A-4. Non-Architectural Performance Events In the Processor Core for Intel Core i7 Processor and Intel Xeon Processor 5500 Series**

| Event Num. | Umask Value | Event Mask Mnemonic          | Description                                                                                                                                                                            | Comment |
|------------|-------------|------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------|
| 24H        | 08H         | L2_RQSTS.RFO_MISS            | Counts the number of store RFO requests that miss the L2 cache. L2 RFO requests include both L1D demand RFO misses as well as L1D RFO prefetches.                                      |         |
| 24H        | 0CH         | L2_RQSTS.RFOS                | Counts all L2 store RFO requests. L2 RFO requests include both L1D demand RFO misses as well as L1D RFO prefetches.                                                                    |         |
| 24H        | 10H         | L2_RQSTS.IFETCH_HIT          | Counts number of instruction fetches that hit the L2 cache. L2 instruction fetches include both L1I demand misses as well as L1I instruction prefetches.                               |         |
| 24H        | 20H         | L2_RQSTS.IFETCH_MISS         | Counts number of instruction fetches that miss the L2 cache. L2 instruction fetches include both L1I demand misses as well as L1I instruction prefetches.                              |         |
| 24H        | 30H         | L2_RQSTS.IFETCHES            | Counts all instruction fetches. L2 instruction fetches include both L1I demand misses as well as L1I instruction prefetches.                                                           |         |
| 24H        | 40H         | L2_RQSTS.PREFETCH_HIT        | Counts L2 prefetch hits for both code and data.                                                                                                                                        |         |
| 24H        | 80H         | L2_RQSTS.PREFETCH_MISS       | Counts L2 prefetch misses for both code and data.                                                                                                                                      |         |
| 24H        | COH         | L2_RQSTS.PREFETCHES          | Counts all L2 prefetches for both code and data.                                                                                                                                       |         |
| 24H        | AAH         | L2_RQSTS.MISS                | Counts all L2 misses for both code and data.                                                                                                                                           |         |
| 24H        | FFH         | L2_RQSTS.REFERENCES          | Counts all L2 requests for both code and data.                                                                                                                                         |         |
| 26H        | 01H         | L2_DATA_RQSTS.DEMAND_I_STATE | Counts number of L2 data demand loads where the cache line to be loaded is in the I (invalid) state, i.e. a cache miss. L2 demand loads are both L1D demand misses and L1D prefetches. |         |

## PERFORMANCE-MONITORING EVENTS

**Table A-4. Non-Architectural Performance Events In the Processor Core for Intel Core i7 Processor and Intel Xeon Processor 5500 Series**

| Event Num. | Umask Value | Event Mask Mnemonic            | Description                                                                                                                                                                                           | Comment |
|------------|-------------|--------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------|
| 26H        | 02H         | L2_DATA_RQSTS.DEMAND.S_STATE   | Counts number of L2 data demand loads where the cache line to be loaded is in the S (shared) state. L2 demand loads are both L1D demand misses and L1D prefetches.                                    |         |
| 26H        | 04H         | L2_DATA_RQSTS.DEMAND.E_STATE   | Counts number of L2 data demand loads where the cache line to be loaded is in the E (exclusive) state. L2 demand loads are both L1D demand misses and L1D prefetches.                                 |         |
| 26H        | 08H         | L2_DATA_RQSTS.DEMAND.M_STATE   | Counts number of L2 data demand loads where the cache line to be loaded is in the M (modified) state. L2 demand loads are both L1D demand misses and L1D prefetches.                                  |         |
| 26H        | 0FH         | L2_DATA_RQSTS.DEMAND.MESI      | Counts all L2 data demand requests. L2 demand loads are both L1D demand misses and L1D prefetches.                                                                                                    |         |
| 26H        | 10H         | L2_DATA_RQSTS.PREFETCH.I_STATE | Counts number of L2 prefetch data loads where the cache line to be loaded is in the I (invalid) state, i.e. a cache miss.                                                                             |         |
| 26H        | 20H         | L2_DATA_RQSTS.PREFETCH.S_STATE | Counts number of L2 prefetch data loads where the cache line to be loaded is in the S (shared) state. A prefetch RFO will miss on an S state line, while a prefetch read will hit on an S state line. |         |
| 26H        | 40H         | L2_DATA_RQSTS.PREFETCH.E_STATE | Counts number of L2 prefetch data loads where the cache line to be loaded is in the E (exclusive) state.                                                                                              |         |
| 26H        | 80H         | L2_DATA_RQSTS.PREFETCH.M_STATE | Counts number of L2 prefetch data loads where the cache line to be loaded is in the M (modified) state.                                                                                               |         |
| 26H        | FOH         | L2_DATA_RQSTS.PREFETCH.MESI    | Counts all L2 prefetch requests.                                                                                                                                                                      |         |
| 26H        | FFH         | L2_DATA_RQSTS.ANY              | Counts all L2 data requests.                                                                                                                                                                          |         |

**Table A-4. Non-Architectural Performance Events In the Processor Core for Intel Core i7 Processor and Intel Xeon Processor 5500 Series**

| Event Num. | Umask Value | Event Mask Mnemonic   | Description                                                                                                                                                                       | Comment                      |
|------------|-------------|-----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------|
| 27H        | 01H         | L2_WRITE.RFO.I_STATE  | Counts number of L2 demand store RFO requests where the cache line to be loaded is in the I (invalid) state, i.e, a cache miss. The L1D prefetcher does not issue a RFO prefetch. | This is a demand RFO request |
| 27H        | 02H         | L2_WRITE.RFO.S_STATE  | Counts number of L2 store RFO requests where the cache line to be loaded is in the S (shared) state. The L1D prefetcher does not issue a RFO prefetch.                            | This is a demand RFO request |
| 27H        | 08H         | L2_WRITE.RFO.M_STATE  | Counts number of L2 store RFO requests where the cache line to be loaded is in the M (modified) state. The L1D prefetcher does not issue a RFO prefetch.                          | This is a demand RFO request |
| 27H        | 0EH         | L2_WRITE.RFO.HIT      | Counts number of L2 store RFO requests where the cache line to be loaded is in either the S, E or M states. The L1D prefetcher does not issue a RFO prefetch.                     | This is a demand RFO request |
| 27H        | 0FH         | L2_WRITE.RFO.MESI     | Counts all L2 store RFO requests. The L1D prefetcher does not issue a RFO prefetch.                                                                                               | This is a demand RFO request |
| 27H        | 10H         | L2_WRITE.LOCK.I_STATE | Counts number of L2 demand lock RFO requests where the cache line to be loaded is in the I (invalid) state, i.e. a cache miss.                                                    |                              |
| 27H        | 20H         | L2_WRITE.LOCK.S_STATE | Counts number of L2 lock RFO requests where the cache line to be loaded is in the S (shared) state.                                                                               |                              |
| 27H        | 40H         | L2_WRITE.LOCK.E_STATE | Counts number of L2 demand lock RFO requests where the cache line to be loaded is in the E (exclusive) state.                                                                     |                              |
| 27H        | 80H         | L2_WRITE.LOCK.M_STATE | Counts number of L2 demand lock RFO requests where the cache line to be loaded is in the M (modified) state.                                                                      |                              |

## PERFORMANCE-MONITORING EVENTS

**Table A-4. Non-Architectural Performance Events In the Processor Core for Intel Core i7 Processor and Intel Xeon Processor 5500 Series**

| Event Num. | Umask Value | Event Mask Mnemonic    | Description                                                                                                                                                                                                                                                                                                                                                                          | Comment       |
|------------|-------------|------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------|
| 27H        | EOH         | L2_WRITE.LOCK.HIT      | Counts number of L2 demand lock RFO requests where the cache line to be loaded is in either the S, E, or M state.                                                                                                                                                                                                                                                                    |               |
| 27H        | FOH         | L2_WRITE.LOCK.MESI     | Counts all L2 demand lock RFO requests.                                                                                                                                                                                                                                                                                                                                              |               |
| 28H        | 01H         | L1D_WB_L2.I_STATE      | Counts number of L1 writebacks to the L2 where the cache line to be written is in the I (invalid) state, i.e. a cache miss.                                                                                                                                                                                                                                                          |               |
| 28H        | 02H         | L1D_WB_L2.S_STATE      | Counts number of L1 writebacks to the L2 where the cache line to be written is in the S state.                                                                                                                                                                                                                                                                                       |               |
| 28H        | 04H         | L1D_WB_L2.E_STATE      | Counts number of L1 writebacks to the L2 where the cache line to be written is in the E (exclusive) state.                                                                                                                                                                                                                                                                           |               |
| 28H        | 08H         | L1D_WB_L2.M_STATE      | Counts number of L1 writebacks to the L2 where the cache line to be written is in the M (modified) state.                                                                                                                                                                                                                                                                            |               |
| 28H        | 0FH         | L1D_WB_L2.MESI         | Counts all L1 writebacks to the L2 .                                                                                                                                                                                                                                                                                                                                                 |               |
| 2EH        | 4FH         | L3_LAT_CACHE.REFERENCE | This event counts requests originating from the core that reference a cache line in the last level cache. The event count includes speculative traffic but excludes cache line fills due to a L2 hardware-prefetch. Because cache hierarchy, cache sizes and other implementation-specific characteristics; value comparison to estimate performance differences is not recommended. | see Table A-1 |

## PERFORMANCE-MONITORING EVENTS

**Table A-4. Non-Architectural Performance Events In the Processor Core for Intel Core i7 Processor and Intel Xeon Processor 5500 Series**

| Event Num. | Umask Value | Event Mask Mnemonic       | Description                                                                                                                                                                                                                                                                                                                                                       | Comment           |
|------------|-------------|---------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------|
| 2EH        | 41H         | L3_LAT_CACHE.MISS         | This event counts each cache miss condition for references to the last level cache. The event count may include speculative traffic but excludes cache line fills due to L2 hardware-prefetches. Because cache hierarchy, cache sizes and other implementation-specific characteristics; value comparison to estimate performance differences is not recommended. | see Table A-1     |
| 3CH        | 00H         | CPU_CLK_UNHALTED.THREAD_P | Counts the number of thread cycles while the thread is not in a halt state. The thread enters the halt state when it is running the HLT instruction. The core frequency may change from time to time due to power or thermal throttling.                                                                                                                          | see Table A-1     |
| 3CH        | 01H         | CPU_CLK_UNHALTED.REF_P    | Increments at the frequency of TSC when not halted.                                                                                                                                                                                                                                                                                                               | see Table A-1     |
| 40H        | 01H         | L1D_CACHE_LD.I_STATE      | Counts L1 data cache read requests where the cache line to be loaded is in the I (invalid) state, i.e. the read request missed the cache.                                                                                                                                                                                                                         | Counter 0, 1 only |
| 40H        | 02H         | L1D_CACHE_LD.S_STATE      | Counts L1 data cache read requests where the cache line to be loaded is in the S (shared) state.                                                                                                                                                                                                                                                                  | Counter 0, 1 only |
| 40H        | 04H         | L1D_CACHE_LD.E_STATE      | Counts L1 data cache read requests where the cache line to be loaded is in the E (exclusive) state.                                                                                                                                                                                                                                                               | Counter 0, 1 only |
| 40H        | 08H         | L1D_CACHE_LD.M_STATE      | Counts L1 data cache read requests where the cache line to be loaded is in the M (modified) state.                                                                                                                                                                                                                                                                | Counter 0, 1 only |
| 40H        | 0FH         | L1D_CACHE_LD.MESI         | Counts L1 data cache read requests.                                                                                                                                                                                                                                                                                                                               | Counter 0, 1 only |
| 41H        | 02H         | L1D_CACHE_STS_STATE       | Counts L1 data cache store RFO requests where the cache line to be loaded is in the S (shared) state.                                                                                                                                                                                                                                                             | Counter 0, 1 only |

## PERFORMANCE-MONITORING EVENTS

**Table A-4. Non-Architectural Performance Events In the Processor Core for Intel Core i7 Processor and Intel Xeon Processor 5500 Series**

| Event Num. | Umask Value | Event Mask Mnemonic        | Description                                                                                                                                                                                                                                                                                                 | Comment                                                                                 |
|------------|-------------|----------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------|
| 41H        | 04H         | L1D_CACHE_ST.E_STATE       | Counts L1 data cache store RFO requests where the cache line to be loaded is in the E (exclusive) state.                                                                                                                                                                                                    | Counter 0, 1 only                                                                       |
| 41H        | 08H         | L1D_CACHE_ST.M_STATE       | Counts L1 data cache store RFO requests where cache line to be loaded is in the M (modified) state.                                                                                                                                                                                                         | Counter 0, 1 only                                                                       |
| 42H        | 01H         | L1D_CACHE_LOCK_HIT         | Counts retired load locks that hit in the L1 data cache or hit in an already allocated fill buffer. The lock portion of the load lock transaction must hit in the L1D.                                                                                                                                      | The initial load will pull the lock into the L1 data cache. Counter 0, 1 only           |
| 42H        | 02H         | L1D_CACHE_LOCK_S_STATE     | Counts L1 data cache retired load locks that hit the target cache line in the shared state.                                                                                                                                                                                                                 | Counter 0, 1 only                                                                       |
| 42H        | 04H         | L1D_CACHE_LOCK_E_STATE     | Counts L1 data cache retired load locks that hit the target cache line in the exclusive state.                                                                                                                                                                                                              | Counter 0, 1 only                                                                       |
| 42H        | 08H         | L1D_CACHE_LOCK_M_STATE     | Counts L1 data cache retired load locks that hit the target cache line in the modified state.                                                                                                                                                                                                               | Counter 0, 1 only                                                                       |
| 43H        | 01H         | L1D_ALL_REF.ANY            | Counts all references (uncached, speculated and retired) to the L1 data cache, including all loads and stores with any memory types. The event counts memory accesses only when they are actually performed. For example, a load blocked by unknown store address and later performed is only counted once. | The event does not include non-memory accesses, such as I/O accesses. Counter 0, 1 only |
| 43H        | 02H         | L1D_ALL_REF.CACHEABLE      | Counts all data reads and writes (speculated and retired) from cacheable memory, including locked operations.                                                                                                                                                                                               | Counter 0, 1 only                                                                       |
| 49H        | 01H         | DTLB_MISSES.ANY            | Counts the number of misses in the STLB which causes a page walk.                                                                                                                                                                                                                                           |                                                                                         |
| 49H        | 02H         | DTLB_MISSES.WALK_COMPLETED | Counts number of misses in the STLB which resulted in a completed page walk.                                                                                                                                                                                                                                |                                                                                         |

**Table A-4. Non-Architectural Performance Events In the Processor Core for Intel Core i7 Processor and Intel Xeon Processor 5500 Series**

| Event Num. | Umask Value | Event Mask Mnemonic              | Description                                                                                                                                                                                                                                                                                                                                           | Comment |
|------------|-------------|----------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------|
| 49H        | 10H         | DTLB_MISSES.STLB_HIT             | Counts the number of DTLB first level misses that hit in the second level TLB. This event is only relevant if the core contains multiple DTLB levels.                                                                                                                                                                                                 |         |
| 49H        | 20H         | DTLB_MISSES.PDE_MISS             | Number of DTLB misses caused by low part of address, includes references to 2M pages because 2M pages do not use the PDE.                                                                                                                                                                                                                             |         |
| 49H        | 80H         | DTLB_MISSES.LARGE_WALK_COMPLETED | Counts number of misses in the STLB which resulted in a completed page walk for large pages.                                                                                                                                                                                                                                                          |         |
| 4CH        | 01H         | LOAD_HIT_PRE                     | Counts load operations sent to the L1 data cache while a previous SSE prefetch instruction to the same cache line has started prefetching but has not yet finished.                                                                                                                                                                                   |         |
| 4EH        | 01H         | L1D_PREFETCH.REQUESTS            | Counts number of hardware prefetch requests dispatched out of the prefetch FIFO.                                                                                                                                                                                                                                                                      |         |
| 4EH        | 02H         | L1D_PREFETCH.MISS                | Counts number of hardware prefetch requests that miss the L1D. There are two prefetchers in the L1D. A streamer, which predicts lines sequentially after this one should be fetched, and the IP prefetcher that remembers access patterns for the current instruction. The streamer prefetcher stops on an L1D hit, while the IP prefetcher does not. |         |
| 4EH        | 04H         | L1D_PREFETCH.TRIGGERS            | Counts number of prefetch requests triggered by the Finite State Machine and pushed into the prefetch FIFO. Some of the prefetch requests are dropped due to overwrites or competition between the IP index prefetcher and streamer prefetcher. The prefetch FIFO contains 4 entries.                                                                 |         |

## PERFORMANCE-MONITORING EVENTS

**Table A-4. Non-Architectural Performance Events In the Processor Core for Intel Core i7 Processor and Intel Xeon Processor 5500 Series**

| Event Num. | Umask Value | Event Mask Mnemonic            | Description                                                                                                                                                                                                                           | Comment                                                                                                                       |
|------------|-------------|--------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------|
| 51H        | 01H         | L1D.REPL                       | Counts the number of lines brought into the L1 data cache.                                                                                                                                                                            | Counter 0, 1 only                                                                                                             |
| 51H        | 02H         | L1D.M_REPL                     | Counts the number of modified lines brought into the L1 data cache.                                                                                                                                                                   | Counter 0, 1 only                                                                                                             |
| 51H        | 04H         | L1D.M_EVICT                    | Counts the number of modified lines evicted from the L1 data cache due to replacement.                                                                                                                                                | Counter 0, 1 only                                                                                                             |
| 51H        | 08H         | L1D.M_SNOOP_EVICT              | Counts the number of modified lines evicted from the L1 data cache due to snoop HITM intervention.                                                                                                                                    | Counter 0, 1 only                                                                                                             |
| 52H        | 01H         | L1D_CACHE_PREFETCH_LOCK_FB_HIT | Counts the number of cacheable load lock speculated instructions accepted into the fill buffer.                                                                                                                                       |                                                                                                                               |
| 53H        | 01H         | L1D_CACHE_LOCK_FILL_HIT        | Counts the number of cacheable load lock speculated or retired instructions accepted into the fill buffer.                                                                                                                            |                                                                                                                               |
| 63H        | 01H         | CACHE_LOCK_CYCLE_S.L1D_L2      | Cycle count during which the L1D and L2 are locked. A lock is asserted when there is a locked memory access, due to uncacheable memory, a locked operation that spans two cache lines, or a page walk from an uncacheable page table. | Counter 0, 1 only. L1D and L2 locks have a very high performance penalty and it is highly recommended to avoid such accesses. |
| 63H        | 02H         | CACHE_LOCK_CYCLE_S.L1D         | Counts the number of cycles that cacheline in the L1 data cache unit is locked.                                                                                                                                                       | Counter 0, 1 only.                                                                                                            |
| 6CH        | 01H         | IO_TRANSACTIONS                | Counts the number of completed I/O transactions.                                                                                                                                                                                      |                                                                                                                               |
| 80H        | 01H         | L1I.HITS                       | Counts all instruction fetches that hit the L1 instruction cache.                                                                                                                                                                     |                                                                                                                               |

**Table A-4. Non-Architectural Performance Events In the Processor Core for Intel Core i7 Processor and Intel Xeon Processor 5500 Series**

| Event Num. | Umask Value | Event Mask Mnemonic        | Description                                                                                                                                                                                                                                                          | Comment |
|------------|-------------|----------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------|
| 80H        | 02H         | L1I.MISSES                 | Counts all instruction fetches that miss the L1I cache. This includes instruction cache misses, streaming buffer misses, victim cache misses and uncacheable fetches. An instruction fetch miss is counted only once and not once for every cycle it is outstanding. |         |
| 80H        | 03H         | L1I.READS                  | Counts all instruction fetches, including uncacheable fetches that bypass the L1I.                                                                                                                                                                                   |         |
| 80H        | 04H         | L1I.CYCLES_STALLED         | Cycle counts for which an instruction fetch stalls due to a L1I cache miss, ITLB miss or ITLB fault.                                                                                                                                                                 |         |
| 82H        | 01H         | LARGE_ITLB.HIT             | Counts number of large ITLB hits.                                                                                                                                                                                                                                    |         |
| 85H        | 01H         | ITLB_MISSES.ANY            | Counts the number of misses in all levels of the ITLB which causes a page walk.                                                                                                                                                                                      |         |
| 85H        | 02H         | ITLB_MISSES.WALK_COMPLETED | Counts number of misses in all levels of the ITLB which resulted in a completed page walk.                                                                                                                                                                           |         |
| 87H        | 01H         | ILD_STALL.LCP              | Cycles Instruction Length Decoder stalls due to length changing prefixes: 66, 67 or REX.W (for EM64T) instructions which change the length of the decoded instruction.                                                                                               |         |
| 87H        | 02H         | ILD_STALL.MRU              | Instruction Length Decoder stall cycles due to Brand Prediction Unit (PBU) Most Recently Used (MRU) bypass.                                                                                                                                                          |         |
| 87H        | 04H         | ILD_STALL.IQ_FULL          | Stall cycles due to a full instruction queue.                                                                                                                                                                                                                        |         |
| 87H        | 08H         | ILD_STALL.REGEN            | Counts the number of regen stalls.                                                                                                                                                                                                                                   |         |
| 87H        | 0FH         | ILD_STALL.ANY              | Counts any cycles the Instruction Length Decoder is stalled.                                                                                                                                                                                                         |         |

## PERFORMANCE-MONITORING EVENTS

**Table A-4. Non-Architectural Performance Events In the Processor Core for Intel Core i7 Processor and Intel Xeon Processor 5500 Series**

| Event Num. | Umask Value | Event Mask Mnemonic             | Description                                                                                                                                                                                                                                       | Comment |
|------------|-------------|---------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------|
| 88H        | 01H         | BR_INST_EXEC.COND               | Counts the number of conditional near branch instructions executed, but not necessarily retired.                                                                                                                                                  |         |
| 88H        | 02H         | BR_INST_EXEC.DIRECT             | Counts all unconditional near branch instructions excluding calls and indirect branches.                                                                                                                                                          |         |
| 88H        | 04H         | BR_INST_EXEC.INDIRECT_NON_CALL  | Counts the number of executed indirect near branch instructions that are not calls.                                                                                                                                                               |         |
| 88H        | 07H         | BR_INST_EXEC.NON_CALLS          | Counts all non call near branch instructions executed, but not necessarily retired.                                                                                                                                                               |         |
| 88H        | 08H         | BR_INST_EXEC.RETURN_NEAR        | Counts indirect near branches that have a return mnemonic.                                                                                                                                                                                        |         |
| 88H        | 10H         | BR_INST_EXEC.DIRECT_NEAR_CALL   | Counts unconditional near call branch instructions, excluding non call branch, executed.                                                                                                                                                          |         |
| 88H        | 20H         | BR_INST_EXEC.INDIRECT_NEAR_CALL | Counts indirect near calls, including both register and memory indirect, executed.                                                                                                                                                                |         |
| 88H        | 30H         | BR_INST_EXEC.NEAR_CALLS         | Counts all near call branches executed, but not necessarily retired.                                                                                                                                                                              |         |
| 88H        | 40H         | BR_INST_EXEC.TAKEN              | Counts taken near branches executed, but not necessarily retired.                                                                                                                                                                                 |         |
| 88H        | 7FH         | BR_INST_EXEC.ANY                | Counts all near executed branches (not necessarily retired). This includes only instructions and not micro-op branches. Frequent branching is not necessarily a major performance issue. However frequent branch mispredictions may be a problem. |         |
| 89H        | 01H         | BR_MISP_EXEC.COND               | Counts the number of mispredicted conditional near branch instructions executed, but not necessarily retired.                                                                                                                                     |         |

**Table A-4. Non-Architectural Performance Events In the Processor Core for Intel Core i7 Processor and Intel Xeon Processor 5500 Series**

| Event Num. | Umask Value | Event Mask Mnemonic             | Description                                                                                                                   | Comment |
|------------|-------------|---------------------------------|-------------------------------------------------------------------------------------------------------------------------------|---------|
| 89H        | 02H         | BR_MISP_EXEC.DIRECT             | Counts mispredicted macro unconditional near branch instructions, excluding calls and indirect branches (should always be 0). |         |
| 89H        | 04H         | BR_MISP_EXEC.INDIRECT_NON_CALL  | Counts the number of executed mispredicted indirect near branch instructions that are not calls.                              |         |
| 89H        | 07H         | BR_MISP_EXEC.NON_CALLS          | Counts mispredicted non call near branches executed, but not necessarily retired.                                             |         |
| 89H        | 08H         | BR_MISP_EXEC.RETURN_NEAR        | Counts mispredicted indirect branches that have a rear return mnemonic.                                                       |         |
| 89H        | 10H         | BR_MISP_EXEC.DIRECT_NEAR_CALL   | Counts mispredicted non-indirect near calls executed, (should always be 0).                                                   |         |
| 89H        | 20H         | BR_MISP_EXEC.INDIRECT_NEAR_CALL | Counts mispredicted indirect near calls executed, including both register and memory indirect.                                |         |
| 89H        | 30H         | BR_MISP_EXEC.NEAR_CALLS         | Counts all mispredicted near call branches executed, but not necessarily retired.                                             |         |
| 89H        | 40H         | BR_MISP_EXEC.TAKEN              | Counts executed mispredicted near branches that are taken, but not necessarily retired.                                       |         |
| 89H        | 7FH         | BR_MISP_EXEC.ANY                | Counts the number of mispredicted near branch instructions that were executed, but not necessarily retired.                   |         |

## PERFORMANCE-MONITORING EVENTS

**Table A-4. Non-Architectural Performance Events In the Processor Core for Intel Core i7 Processor and Intel Xeon Processor 5500 Series**

| Event Num. | Umask Value | Event Mask Mnemonic      | Description                                                                                                                                                                                                                                                                                                                                                                                                       | Comment                                                                                      |
|------------|-------------|--------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------|
| A2H        | 01H         | RESOURCE_STALLS.ANY      | Counts the number of Allocator resource related stalls. Includes register renaming buffer entries, memory buffer entries. In addition to resource related stalls, this event counts some other events. Includes stalls arising during branch misprediction recovery, such as if retirement of the mispredicted branch is delayed and stalls arising while store buffer is draining from synchronizing operations. | Does not include stalls due to SuperQ (off core) queue full, too many cache misses, etc.     |
| A2H        | 02H         | RESOURCE_STALLS.LOAD     | Counts the cycles of stall due to lack of load buffer for load operation.                                                                                                                                                                                                                                                                                                                                         |                                                                                              |
| A2H        | 04H         | RESOURCE_STALLS.RS_FULL  | This event counts the number of cycles when the number of instructions in the pipeline waiting for execution reaches the limit the processor can handle. A high count of this event indicates that there are long latency operations in the pipe (possibly load and store operations that miss the L2 cache, or instructions dependent upon instructions further down the pipeline that have yet to retire).      | When RS is full, new instructions can not enter the reservation station and start execution. |
| A2H        | 08H         | RESOURCE_STALLS.STORE    | This event counts the number of cycles that a resource related stall will occur due to the number of store instructions reaching the limit of the pipeline, (i.e. all store buffers are used). The stall ends when a store instruction commits its data to the cache or memory.                                                                                                                                   |                                                                                              |
| A2H        | 10H         | RESOURCE_STALLS.ROB_FULL | Counts the cycles of stall due to re-order buffer full.                                                                                                                                                                                                                                                                                                                                                           |                                                                                              |
| A2H        | 20H         | RESOURCE_STALLS.FPCW     | Counts the number of cycles while execution was stalled due to writing the floating-point unit (FPU) control word.                                                                                                                                                                                                                                                                                                |                                                                                              |

**Table A-4. Non-Architectural Performance Events In the Processor Core for Intel Core i7 Processor and Intel Xeon Processor 5500 Series**

| Event Num. | Umask Value | Event Mask Mnemonic             | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        | Comment                                |
|------------|-------------|---------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------|
| A2H        | 40H         | RESOURCE_STALLS.MXCSR           | Stalls due to the MXCSR register rename occurring close to a previous MXCSR rename. The MXCSR provides control and status for the MMX registers.                                                                                                                                                                                                                                                                                                                                                                                                   |                                        |
| A2H        | 80H         | RESOURCE_STALLS.OTHER           | Counts the number of cycles while execution was stalled due to other resource issues.                                                                                                                                                                                                                                                                                                                                                                                                                                                              |                                        |
| A6H        | 01H         | MACRO_INSTS.FUSION_NS_DECODED   | Counts the number of instructions decoded that are macro-fused but not necessarily executed or retired.                                                                                                                                                                                                                                                                                                                                                                                                                                            |                                        |
| A7H        | 01H         | BACLEAR_FORCE_IQ                | Counts number of times a BACLEAR was forced by the Instruction Queue. The IQ is also responsible for providing conditional branch prediction direction based on a static scheme and dynamic data provided by the L2 Branch Prediction Unit. If the conditional branch target is not found in the Target Array and the IQ predicts that the branch is taken, then the IQ will force the Branch Address Calculator to issue a BACLEAR. Each BACLEAR asserted by the BAC generates approximately an 8 cycle bubble in the instruction fetch pipeline. |                                        |
| A8H        | 01H         | LSD.UOPS                        | Counts the number of micro-ops delivered by loop stream detector.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  | Use cmask=1 and invert to count cycles |
| AEH        | 01H         | ITLB_FLUSH                      | Counts the number of ITLB flushes.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |                                        |
| BOH        | 40H         | OFFCORE_REQUEST.S.L1D_WRITEBACK | Counts number of L1D writebacks to the uncore.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |                                        |
| B1H        | 01H         | UOPS_EXECUTED.PORT0             | Counts number of Uops executed that were issued on port 0. Port 0 handles integer arithmetic, SIMD and FP add Uops.                                                                                                                                                                                                                                                                                                                                                                                                                                |                                        |

## PERFORMANCE-MONITORING EVENTS

**Table A-4. Non-Architectural Performance Events In the Processor Core for Intel Core i7 Processor and Intel Xeon Processor 5500 Series**

| Event Num. | Umask Value | Event Mask Mnemonic                        | Description                                                                                                                                                                                                                                       | Comment |
|------------|-------------|--------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------|
| B1H        | 02H         | UOPS_EXECUTED.PO RT1                       | Counts number of Uops executed that were issued on port 1. Port 1 handles integer arithmetic, SIMD, integer shift, FP multiply and FP divide Uops.                                                                                                |         |
| B1H        | 04H         | UOPS_EXECUTED.PO RT2_CORE                  | Counts number of Uops executed that were issued on port 2. Port 2 handles the load Uops. This is a core count only and can not be collected per thread.                                                                                           |         |
| B1H        | 08H         | UOPS_EXECUTED.PO RT3_CORE                  | Counts number of Uops executed that were issued on port 3. Port 3 handles store Uops. This is a core count only and can not be collected per thread.                                                                                              |         |
| B1H        | 10H         | UOPS_EXECUTED.PO RT4_CORE                  | Counts number of Uops executed that were issued on port 4. Port 4 handles the value to be stored for the store Uops issued on port 3. This is a core count only and can not be collected per thread.                                              |         |
| B1H        | 1FH         | UOPS_EXECUTED.CO RE_ACTIVE_CYCLES_NO_PORT5 | Counts cycles when the Uops executed were issued from any ports except port 5. Use Cmask=1 for active cycles; Cmask=0 for weighted cycles; Use CMask=1, Invert=1 to count P0-4 stalled cycles Use Cmask=1, Edge=1, Invert=1 to count P0-4 stalls. |         |
| B1H        | 20H         | UOPS_EXECUTED.PO RT5                       | Counts number of Uops executed that were issued on port 5.                                                                                                                                                                                        |         |
| B1H        | 3FH         | UOPS_EXECUTED.CO RE_ACTIVE_CYCLES          | Counts cycles when the Uops are executing. Use Cmask=1 for active cycles; Cmask=0 for weighted cycles; Use CMask=1, Invert=1 to count P0-4 stalled cycles Use Cmask=1, Edge=1, Invert=1 to count P0-4 stalls.                                     |         |

**Table A-4. Non-Architectural Performance Events In the Processor Core for Intel Core i7 Processor and Intel Xeon Processor 5500 Series**

| Event Num. | Umask Value | Event Mask Mnemonic       | Description                                                                                                                                                                                                                     | Comment                                                                                                   |
|------------|-------------|---------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------|
| B1H        | 40H         | UOPS_EXECUTED.PO RT015    | Counts number of Uops executed that where issued on port 0, 1, or 5.                                                                                                                                                            | use cmask=1, invert=1 to count stall cycles                                                               |
| B1H        | 80H         | UOPS_EXECUTED.PO RT234    | Counts number of Uops executed that where issued on port 2, 3, or 4.                                                                                                                                                            |                                                                                                           |
| B2H        | 01H         | OFFCORE_REQUEST_S_SQ_FULL | Counts number of cycles the SQ is full to handle off-core requests.                                                                                                                                                             |                                                                                                           |
| B7H        | 01H         | OFF_CORE_RESPONSE_E_0     | see Section 30.6.1.3, "Off-core Response Performance Monitoring in the Processor Core".                                                                                                                                         | Requires programming MSR 01A6H                                                                            |
| B8H        | 01H         | SNOOP_RESPONSE.HIT        | Counts HIT snoop response sent by this thread in response to a snoop request.                                                                                                                                                   |                                                                                                           |
| B8H        | 02H         | SNOOP_RESPONSE.HITE       | Counts HIT E snoop response sent by this thread in response to a snoop request.                                                                                                                                                 |                                                                                                           |
| B8H        | 04H         | SNOOP_RESPONSE.HITM       | Counts HIT M snoop response sent by this thread in response to a snoop request.                                                                                                                                                 |                                                                                                           |
| BBH        | 01H         | OFF_CORE_RESPONSE_E_1     | See Section 30.7, "Performance Monitoring for Processors Based on Intel® Microarchitecture Code Name Westmere".                                                                                                                 | Requires programming MSR 01A7H                                                                            |
| COH        | 01H         | INST_RETIREDA.NY_P        | See Table A-1<br>Notes: INST_RETIREDA.NY is counted by a designated fixed counter. INST_RETIREDA.NY_P is counted by a programmable counter and is an architectural performance event. Event is supported if CPUID.A.EBX[1] = 0. | Counting:<br>Faulting executions of GETSEC/VM entry/VM Exit/MWait will not count as retired instructions. |
| COH        | 02H         | INST_RETIREDA.X87         | Counts the number of MMX instructions retired.                                                                                                                                                                                  |                                                                                                           |

## PERFORMANCE-MONITORING EVENTS

**Table A-4. Non-Architectural Performance Events In the Processor Core for Intel Core i7 Processor and Intel Xeon Processor 5500 Series**

| Event Num. | Umask Value | Event Mask Mnemonic            | Description                                                                                                                                                                                                                                                                                                       | Comment                                                         |
|------------|-------------|--------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------|
| COH        | 04H         | INST_RETIREDE.MMX              | Counts the number of floating point computational operations retired: floating point computational operations executed by the assist handler and sub-operations of complex floating point instructions like transcendental instructions.                                                                          |                                                                 |
| C2H        | 01H         | UOPS_RETIREDE.ANY              | Counts the number of micro-ops retired, (macro-fused=1, micro-fused=2, others=1; maximum count of 8 per cycle). Most instructions are composed of one or two micro-ops. Some instructions are decoded into longer sequences such as repeat instructions, floating point transcendental instructions, and assists. | Use cmask=1 and invert to count active cycles or stalled cycles |
| C2H        | 02H         | UOPS_RETIREDE.RETI RE_SLOTS    | Counts the number of retirement slots used each cycle.                                                                                                                                                                                                                                                            |                                                                 |
| C2H        | 04H         | UOPS_RETIREDE.MAC RO_FUSED     | Counts number of macro-fused uops retired.                                                                                                                                                                                                                                                                        |                                                                 |
| C3H        | 01H         | MACHINE_CLEARSE.CY CLES        | Counts the cycles machine clear is asserted.                                                                                                                                                                                                                                                                      |                                                                 |
| C3H        | 02H         | MACHINE_CLEARSE.M EM_ORDER     | Counts the number of machine clears due to memory order conflicts.                                                                                                                                                                                                                                                |                                                                 |
| C3H        | 04H         | MACHINE_CLEARSE.S MC           | Counts the number of times that a program writes to a code section. Self-modifying code causes a severe penalty in all Intel 64 and IA-32 processors. The modified cache line is written back to the L2 and L3 caches.                                                                                            |                                                                 |
| C4H        | 00H         | BR_INST_RETIREDE.A LL_BRANCHES | Branch instructions at retirement                                                                                                                                                                                                                                                                                 | See Table A-1                                                   |
| C4H        | 01H         | BR_INST_RETIREDE.C ONDITIONAL  | Counts the number of conditional branch instructions retired.                                                                                                                                                                                                                                                     |                                                                 |

**Table A-4. Non-Architectural Performance Events In the Processor Core for Intel Core i7 Processor and Intel Xeon Processor 5500 Series**

| Event Num. | Umask Value | Event Mask Mnemonic                            | Description                                                                                                                                                                                      | Comment       |
|------------|-------------|------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------|
| C4H        | 02H         | BR_INST_RETIRE.N<br>EAR_CALL                   | Counts the number of direct & indirect near unconditional calls retired.                                                                                                                         |               |
| C4H        | 04H         | BR_INST_RETIRE.A<br>LL_BRANCHES                | Counts the number of branch instructions retired.                                                                                                                                                |               |
| C5H        | 00H         | BR_MISP_RETIRE.A<br>LL_BRANCHES                | Mispredicted branch instructions at retirement                                                                                                                                                   | See Table A-1 |
| C5H        | 02H         | BR_MISP_RETIRE.N<br>EAR_CALL                   | Counts mispredicted direct & indirect near unconditional retired calls.                                                                                                                          |               |
| C7H        | 01H         | SSEX_UOPS_RETIRE<br>D.PACKED_SINGLE            | Counts SIMD packed single-precision floating point Uops retired.                                                                                                                                 |               |
| C7H        | 02H         | SSEX_UOPS_RETIRE<br>D.SCALAR_SINGLE            | Counts SIMD scalar single-precision floating point Uops retired.                                                                                                                                 |               |
| C7H        | 04H         | SSEX_UOPS_RETIRE<br>D.PACKED_DOUBLE            | Counts SIMD packed double-precision floating point Uops retired.                                                                                                                                 |               |
| C7H        | 08H         | SSEX_UOPS_RETIRE<br>D.SCALAR_DOUBLE            | Counts SIMD scalar double-precision floating point Uops retired.                                                                                                                                 |               |
| C7H        | 10H         | SSEX_UOPS_RETIRE<br>D.VECTOR_INTEGER           | Counts 128-bit SIMD vector integer Uops retired.                                                                                                                                                 |               |
| C8H        | 20H         | ITLB_MISS_RETIRE                               | Counts the number of retired instructions that missed the ITLB when the instruction was fetched.                                                                                                 |               |
| CBH        | 01H         | MEM_LOAD_RETIRE<br>.L1D_HIT                    | Counts number of retired loads that hit the L1 data cache.                                                                                                                                       |               |
| CBH        | 02H         | MEM_LOAD_RETIRE<br>.L2_HIT                     | Counts number of retired loads that hit the L2 data cache.                                                                                                                                       |               |
| CBH        | 04H         | MEM_LOAD_RETIRE<br>.L3_UNSHARED_HIT            | Counts number of retired loads that hit their own, unshared lines in the L3 cache.                                                                                                               |               |
| CBH        | 08H         | MEM_LOAD_RETIRE<br>.OTHER_CORE_L2_HI<br>T_HITM | Counts number of retired loads that hit in a sibling core's L2 (on die core). Since the L3 is inclusive of all cores on the package, this is an L3 hit. This counts both clean or modified hits. |               |

## PERFORMANCE-MONITORING EVENTS

**Table A-4. Non-Architectural Performance Events In the Processor Core for Intel Core i7 Processor and Intel Xeon Processor 5500 Series**

| Event Num. | Umask Value | Event Mask Mnemonic        | Description                                                                                                                                                                                                                                                                                 | Comment |
|------------|-------------|----------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------|
| CBH        | 10H         | MEM_LOAD_RETIRED.L3_MISS   | Counts number of retired loads that miss the L3 cache. The load was satisfied by a remote socket, local memory or an IOH.                                                                                                                                                                   |         |
| CBH        | 40H         | MEM_LOAD_RETIRED.HIT_LFB   | Counts number of retired loads that miss the L1D and the address is located in an allocated line fill buffer and will soon be committed to cache. This is counting secondary L1D misses.                                                                                                    |         |
| CBH        | 80H         | MEM_LOAD_RETIRED.DTLB_MISS | Counts the number of retired loads that missed the DTLB. The DTLB miss is not counted if the load operation causes a fault. This event counts loads from cacheable memory only. The event does not count loads by software prefetches. Counts both primary and secondary misses to the TLB. |         |
| CCH        | 01H         | FP_MMX_TRANS.TO_FPSW       | Counts the first floating-point instruction following any MMX instruction. You can use this event to estimate the penalties for the transitions between floating-point and MMX technology states.                                                                                           |         |
| CCH        | 02H         | FP_MMX_TRANS.TOMMX         | Counts the first MMX instruction following a floating-point instruction. You can use this event to estimate the penalties for the transitions between floating-point and MMX technology states.                                                                                             |         |
| CCH        | 03H         | FP_MMX_TRANS.ANY           | Counts all transitions from floating point to MMX instructions and from MMX instructions to floating point instructions. You can use this event to estimate the penalties for the transitions between floating-point and MMX technology states.                                             |         |

**Table A-4. Non-Architectural Performance Events In the Processor Core for Intel Core i7 Processor and Intel Xeon Processor 5500 Series**

| Event Num. | Umask Value | Event Mask Mnemonic      | Description                                                                                                                                                                                                                                                                                                                                                                                         | Comment |
|------------|-------------|--------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------|
| DOH        | 01H         | MACRO_INSTS.DECODED      | Counts the number of instructions decoded, (but not necessarily executed or retired).                                                                                                                                                                                                                                                                                                               |         |
| D1H        | 02H         | UOPS_DECODED.MS          | Counts the number of Uops decoded by the Microcode Sequencer, MS. The MS delivers uops when the instruction is more than 4 uops long or a microcode assist is occurring.                                                                                                                                                                                                                            |         |
| D1H        | 04H         | UOPS_DECODED.ESP_FOLDING | Counts number of stack pointer (ESP) instructions decoded: push, pop, call, ret, etc. ESP instructions do not generate a Uop to increment or decrement ESP. Instead, they update an ESP_Offset register that keeps track of the delta to the current value of the ESP register.                                                                                                                     |         |
| D1H        | 08H         | UOPS_DECODED.ESP_SYNC    | Counts number of stack pointer (ESP) sync operations where an ESP instruction is corrected by adding the ESP offset register to the current value of the ESP register.                                                                                                                                                                                                                              |         |
| D2H        | 01H         | RAT_STALLS.FLAGS         | Counts the number of cycles during which execution stalled due to several reasons, one of which is a partial flag register stall. A partial register stall may occur when two conditions are met: 1) an instruction modifies some, but not all, of the flags in the flag register and 2) the next instruction, which depends on flags, depends on flags that were not modified by this instruction. |         |
| D2H        | 02H         | RAT_STALLS.REGISTER      | This event counts the number of cycles instruction execution latency became longer than the defined latency because the instruction used a register that was partially written by previous instruction.                                                                                                                                                                                             |         |

## PERFORMANCE-MONITORING EVENTS

**Table A-4. Non-Architectural Performance Events In the Processor Core for Intel Core i7 Processor and Intel Xeon Processor 5500 Series**

| Event Num. | Umask Value | Event Mask Mnemonic      | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                       | Comment |
|------------|-------------|--------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------|
| D2H        | 04H         | RAT_STALLS.ROB_READ_PORT | Counts the number of cycles when ROB read port stalls occurred, which did not allow new micro-ops to enter the out-of-order pipeline. Note that, at this stage in the pipeline, additional stalls may occur at the same cycle and prevent the stalled micro-ops from entering the pipe. In such a case, micro-ops retry entering the execution pipe in the next cycle and the ROB-read port stall is counted again.                                               |         |
| D2H        | 08H         | RAT_STALLS.SCOREBOARD    | Counts the cycles where we stall due to microarchitecturally required serialization. Microcode scoreboarding stalls.                                                                                                                                                                                                                                                                                                                                              |         |
| D2H        | 0FH         | RAT_STALLS.ANY           | Counts all Register Allocation Table stall cycles due to: Cycles when ROB read port stalls occurred, which did not allow new micro-ops to enter the execution pipe. Cycles when partial register stalls occurred Cycles when flag stalls occurred Cycles floating-point unit (FPU) status word stalls occurred. To count each of these conditions separately use the events: RAT_STALLS.ROB_READ_PORT, RAT_STALLS.PARTIAL, RAT_STALLS.FLAGS, and RAT_STALLS.FPSW. |         |
| D4H        | 01H         | SEG_RENAME_STALLS        | Counts the number of stall cycles due to the lack of renaming resources for the ES, DS, FS, and GS segment registers. If a segment is renamed but not retired and a second update to the same segment occurs, a stall occurs in the front-end of the pipeline until the renamed segment retires.                                                                                                                                                                  |         |

**Table A-4. Non-Architectural Performance Events In the Processor Core for Intel Core i7 Processor and Intel Xeon Processor 5500 Series**

| Event Num. | Umask Value | Event Mask Mnemonic | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                              | Comment                                                 |
|------------|-------------|---------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------|
| D5H        | 01H         | ES_REG_RENAMES      | Counts the number of times the ES segment register is renamed.                                                                                                                                                                                                                                                                                                                                                                                                                           |                                                         |
| DBH        | 01H         | UOP_UNFUSION        | Counts unfusion events due to floating point exception to a fused uop.                                                                                                                                                                                                                                                                                                                                                                                                                   |                                                         |
| EOH        | 01H         | BR_INST_DECODED     | Counts the number of branch instructions decoded.                                                                                                                                                                                                                                                                                                                                                                                                                                        |                                                         |
| E5H        | 01H         | BPU_MISSED_CALL_RET | Counts number of times the Branch Prediciton Unit missed predicting a call or return branch.                                                                                                                                                                                                                                                                                                                                                                                             |                                                         |
| E6H        | 01H         | BACLEAR.CLEAR       | Counts the number of times the front end is resteeered, mainly when the Branch Prediction Unit cannot provide a correct prediction and this is corrected by the Branch Address Calculator at the front end. This can occur if the code has many branches such that they cannot be consumed by the BPU. Each BACLEAR asserted by the BAC generates approximately an 8 cycle bubble in the instruction fetch pipeline. The effect on total execution time depends on the surrounding code. |                                                         |
| E6H        | 02H         | BACLEAR.BAD_TARGET  | Counts number of Branch Address Calculator clears (BACLEAR) asserted due to conditional branch instructions in which there was a target hit but the direction was wrong. Each BACLEAR asserted by the BAC generates approximately an 8 cycle bubble in the instruction fetch pipeline.                                                                                                                                                                                                   |                                                         |
| E8H        | 01H         | BPU_CLEAR.EARLY     | Counts early (normal) Branch Prediction Unit clears: BPU predicted a taken branch after incorrectly assuming that it was not taken.                                                                                                                                                                                                                                                                                                                                                      | The BPU clear leads to 2 cycle bubble in the Front End. |

## PERFORMANCE-MONITORING EVENTS

**Table A-4. Non-Architectural Performance Events In the Processor Core for Intel Core i7 Processor and Intel Xeon Processor 5500 Series**

| Event Num. | Umask Value | Event Mask Mnemonic         | Description                                                                                                                              | Comment |
|------------|-------------|-----------------------------|------------------------------------------------------------------------------------------------------------------------------------------|---------|
| E8H        | 02H         | BPU_CLEARSLATE              | Counts late Branch Prediction Unit clears due to Most Recently Used conflicts. The PBU clear leads to a 3 cycle bubble in the Front End. |         |
| F0H        | 01H         | L2_TRANSACTIONS.LOAD        | Counts L2 load operations due to HW prefetch or demand loads.                                                                            |         |
| F0H        | 02H         | L2_TRANSACTIONS.RFO         | Counts L2 RFO operations due to HW prefetch or demand RFOs.                                                                              |         |
| F0H        | 04H         | L2_TRANSACTIONS.IFETCH      | Counts L2 instruction fetch operations due to HW prefetch or demand ifetch.                                                              |         |
| F0H        | 08H         | L2_TRANSACTIONS.PREFETCH    | Counts L2 prefetch operations.                                                                                                           |         |
| F0H        | 10H         | L2_TRANSACTIONS.L1D_WB      | Counts L1D writeback operations to the L2.                                                                                               |         |
| F0H        | 20H         | L2_TRANSACTIONS.FILL        | Counts L2 cache line fill operations due to load, RFO, L1D writeback or prefetch.                                                        |         |
| F0H        | 40H         | L2_TRANSACTIONS.WB          | Counts L2 writeback operations to the L3.                                                                                                |         |
| F0H        | 80H         | L2_TRANSACTIONS.ANY         | Counts all L2 cache operations.                                                                                                          |         |
| F1H        | 02H         | L2_LINES_IN.S_STATE         | Counts the number of cache lines allocated in the L2 cache in the S (shared) state.                                                      |         |
| F1H        | 04H         | L2_LINES_IN.E_STATE         | Counts the number of cache lines allocated in the L2 cache in the E (exclusive) state.                                                   |         |
| F1H        | 07H         | L2_LINES_IN.ANY             | Counts the number of cache lines allocated in the L2 cache.                                                                              |         |
| F2H        | 01H         | L2_LINES_OUT.DEMAND_CLEAN   | Counts L2 clean cache lines evicted by a demand request.                                                                                 |         |
| F2H        | 02H         | L2_LINES_OUT.DEMAND_DIRTY   | Counts L2 dirty (modified) cache lines evicted by a demand request.                                                                      |         |
| F2H        | 04H         | L2_LINES_OUT.PREFETCH_CLEAN | Counts L2 clean cache line evicted by a prefetch request.                                                                                |         |

**Table A-4. Non-Architectural Performance Events In the Processor Core for Intel Core i7 Processor and Intel Xeon Processor 5500 Series**

| Event Num. | Umask Value | Event Mask Mnemonic         | Description                                                                                                                                                                                                                                                                                                                                                                                | Comment |
|------------|-------------|-----------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------|
| F2H        | 08H         | L2_LINES_OUT.PREFETCH_DIRTY | Counts L2 modified cache line evicted by a prefetch request.                                                                                                                                                                                                                                                                                                                               |         |
| F2H        | 0FH         | L2_LINES_OUT.ANY            | Counts all L2 cache lines evicted for any reason.                                                                                                                                                                                                                                                                                                                                          |         |
| F4H        | 10H         | SQ_MISC.SPLIT_LOCK          | Counts the number of SQ lock splits across a cache line.                                                                                                                                                                                                                                                                                                                                   |         |
| F6H        | 01H         | SQ_FULL_STALL_CYCLE         | Counts cycles the Super Queue is full. Neither of the threads on this core will be able to access the uncore.                                                                                                                                                                                                                                                                              |         |
| F7H        | 01H         | FP_ASSIST.ALL               | Counts the number of floating point operations executed that required micro-code assist intervention. Assists are required in the following cases: SSE instructions, (Denormal input when the DAZ flag is off or Underflow result when the FTZ flag is off); x87 instructions, (NaN or denormal are loaded to a register or used as input from memory, Division by 0 or Underflow output). |         |
| F7H        | 02H         | FP_ASSIST.OUTPUT            | Counts number of floating point micro-code assist when the output value (destination register) is invalid.                                                                                                                                                                                                                                                                                 |         |
| F7H        | 04H         | FP_ASSIST.INPUT             | Counts number of floating point micro-code assist when the input value (one of the source operands to an FP instruction) is invalid.                                                                                                                                                                                                                                                       |         |
| FDH        | 01H         | SIMD_INT_64.PACKED_MULTIPLY | Counts number of SIMD integer 64 bit packed multiply operations.                                                                                                                                                                                                                                                                                                                           |         |
| FDH        | 02H         | SIMD_INT_64.PACKED_SHIFT    | Counts number of SIMD integer 64 bit packed shift operations.                                                                                                                                                                                                                                                                                                                              |         |
| FDH        | 04H         | SIMD_INT_64.PACK            | Counts number of SIMD integer 64 bit pack operations.                                                                                                                                                                                                                                                                                                                                      |         |
| FDH        | 08H         | SIMD_INT_64.UNPACK          | Counts number of SIMD integer 64 bit unpack operations.                                                                                                                                                                                                                                                                                                                                    |         |

## PERFORMANCE-MONITORING EVENTS

**Table A-4. Non-Architectural Performance Events In the Processor Core for Intel Core i7 Processor and Intel Xeon Processor 5500 Series**

| Event Num. | Umask Value | Event Mask Mnemonic        | Description                                                    | Comment |
|------------|-------------|----------------------------|----------------------------------------------------------------|---------|
| FDH        | 10H         | SIMD_INT_64.PACKED_LOGICAL | Counts number of SIMD integer 64 bit logical operations.       |         |
| FDH        | 20H         | SIMD_INT_64.PACKED_ARITH   | Counts number of SIMD integer 64 bit arithmetic operations.    |         |
| FDH        | 40H         | SIMD_INT_64.SHUFFLE_MOVE   | Counts number of SIMD integer 64 bit shift or move operations. |         |

Non-architectural Performance monitoring events that are located in the uncore subsystem are implementation specific between different platforms using processors based on Intel microarchitecture code name Nehalem. Processors with CPUID signature of DisplayFamily\_DisplayModel 06\_1AH, 06\_1EH, and 06\_1FH support performance events listed in Table A-5.

**Table A-5. Non-Architectural Performance Events In the Processor Uncore for Intel Core i7 Processor and Intel Xeon Processor 5500 Series**

| Event Num. | Umask Value | Event Mask Mnemonic                         | Description                                                                                                                                        | Comment |
|------------|-------------|---------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------|---------|
| 00H        | 01H         | UNC_GQ_CYCLES_FU_LLREAD_TRACKER             | Uncore cycles Global Queue read tracker is full.                                                                                                   |         |
| 00H        | 02H         | UNC_GQ_CYCLES_FU_LLWRITE_TRACKER            | Uncore cycles Global Queue write tracker is full.                                                                                                  |         |
| 00H        | 04H         | UNC_GQ_CYCLES_FU_LLPEER_PROBE_TRACKER       | Uncore cycles Global Queue peer probe tracker is full. The peer probe tracker queue tracks snoops from the IOH and remote sockets.                 |         |
| 01H        | 01H         | UNC_GQ_CYCLES_NO_T_EMPTY.READ_TRACKER       | Uncore cycles were Global Queue read tracker has at least one valid entry.                                                                         |         |
| 01H        | 02H         | UNC_GQ_CYCLES_NO_T_EMPTY.WRITE_TRACKER      | Uncore cycles were Global Queue write tracker has at least one valid entry.                                                                        |         |
| 01H        | 04H         | UNC_GQ_CYCLES_NO_T_EMPTY.PEER_PROBE_TRACKER | Uncore cycles were Global Queue peer probe tracker has at least one valid entry. The peer probe tracker queue tracks IOH and remote socket snoops. |         |

## PERFORMANCE-MONITORING EVENTS

**Table A-5. Non-Architectural Performance Events In the Processor Uncore for Intel Core i7 Processor and Intel Xeon Processor 5500 Series**

| Event Num. | Umask Value | Event Mask Mnemonic              | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            | Comment |
|------------|-------------|----------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------|
| 03H        | 01H         | UNC_GQ_ALLOC.READ_TRACKER        | Counts the number of tread tracker allocate to deallocate entries. The GQ read tracker allocate to deallocate occupancy count is divided by the count to obtain the average read tracker latency.                                                                                                                                                                                                                                                                                                                                                      |         |
| 03H        | 02H         | UNC_GQ_ALLOC.RT_L3_MISS          | Counts the number GQ read tracker entries for which a full cache line read has missed the L3. The GQ read tracker L3 miss to fill occupancy count is divided by this count to obtain the average cache line read L3 miss latency. The latency represents the time after which the L3 has determined that the cache line has missed. The time between a GQ read tracker allocation and the L3 determining that the cache line has missed is the average L3 hit latency. The total L3 cache line read miss latency is the hit latency + L3 miss latency. |         |
| 03H        | 04H         | UNC_GQ_ALLOC.RT_TO_L3_RESP       | Counts the number of GQ read tracker entries that are allocated in the read tracker queue that hit or miss the L3. The GQ read tracker L3 hit occupancy count is divided by this count to obtain the average L3 hit latency.                                                                                                                                                                                                                                                                                                                           |         |
| 03H        | 08H         | UNC_GQ_ALLOC.RT_TO_RTID_ACQUIRED | Counts the number of GQ read tracker entries that are allocated in the read tracker, have missed in the L3 and have not acquired a Request Transaction ID. The GQ read tracker L3 miss to RTID acquired occupancy count is divided by this count to obtain the average latency for a read L3 miss to acquire an RTID.                                                                                                                                                                                                                                  |         |

## PERFORMANCE-MONITORING EVENTS

**Table A-5. Non-Architectural Performance Events In the Processor Uncore for Intel Core i7 Processor and Intel Xeon Processor 5500 Series**

| Event Num. | Umask Value | Event Mask Mnemonic              | Description                                                                                                                                                                                                                                                                                                      | Comment |
|------------|-------------|----------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------|
| 03H        | 10H         | UNC_GQ_ALLOC.WT_TO_RTID_ACQUIRED | Counts the number of GQ write tracker entries that are allocated in the write tracker, have missed in the L3 and have not acquired a Request Transaction ID. The GQ write tracker L3 miss to RTID occupancy count is divided by this count to obtain the average latency for a write L3 miss to acquire an RTID. |         |
| 03H        | 20H         | UNC_GQ_ALLOC.WRITER_TRACKER      | Counts the number of GQ write tracker entries that are allocated in the write tracker queue that miss the L3. The GQ write tracker occupancy count is divided by the this count to obtain the average L3 write miss latency.                                                                                     |         |
| 03H        | 40H         | UNC_GQ_ALLOC.PEER_PROBE_TRACKER  | Counts the number of GQ peer probe tracker (snoop) entries that are allocated in the peer probe tracker queue that miss the L3. The GQ peer probe occupancy count is divided by this count to obtain the average L3 peer probe miss latency.                                                                     |         |
| 04H        | 01H         | UNC_GQ_DATA.FROM_QPI             | Cycles Global Queue Quickpath Interface input data port is busy importing data from the Quickpath Interface. Each cycle the input port can transfer 8 or 16 bytes of data.                                                                                                                                       |         |
| 04H        | 02H         | UNC_GQ_DATA.FROM_QMC             | Cycles Global Queue Quickpath Memory Interface input data port is busy importing data from the Quickpath Memory Interface. Each cycle the input port can transfer 8 or 16 bytes of data.                                                                                                                         |         |
| 04H        | 04H         | UNC_GQ_DATA.FROM_L3              | Cycles GQ L3 input data port is busy importing data from the Last Level Cache. Each cycle the input port can transfer 32 bytes of data.                                                                                                                                                                          |         |

**Table A-5. Non-Architectural Performance Events In the Processor Uncore for Intel Core i7 Processor and Intel Xeon Processor 5500 Series**

| Event Num. | Umask Value | Event Mask Mnemonic                    | Description                                                                                                                                                                                                                               | Comment |
|------------|-------------|----------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------|
| 04H        | 08H         | UNC_GQ_DATA.FROM_CORES_02              | Cycles GQ Core 0 and 2 input data port is busy importing data from processor cores 0 and 2. Each cycle the input port can transfer 32 bytes of data.                                                                                      |         |
| 04H        | 10H         | UNC_GQ_DATA.FROM_CORES_13              | Cycles GQ Core 1 and 3 input data port is busy importing data from processor cores 1 and 3. Each cycle the input port can transfer 32 bytes of data.                                                                                      |         |
| 05H        | 01H         | UNC_GQ_DATA.TO_QPI_QMC                 | Cycles GQ QPI and QMC output data port is busy sending data to the Quickpath Interface or Quickpath Memory Interface. Each cycle the output port can transfer 32 bytes of data.                                                           |         |
| 05H        | 02H         | UNC_GQ_DATA.TO_L3                      | Cycles GQ L3 output data port is busy sending data to the Last Level Cache. Each cycle the output port can transfer 32 bytes of data.                                                                                                     |         |
| 05H        | 04H         | UNC_GQ_DATA.TO_CORES                   | Cycles GQ Core output data port is busy sending data to the Cores. Each cycle the output port can transfer 32 bytes of data.                                                                                                              |         |
| 06H        | 01H         | UNC_SNP_RESP_TO_LOCAL_HOME.I_STATE     | Number of snoop responses to the local home that L3 does not have the referenced cache line.                                                                                                                                              |         |
| 06H        | 02H         | UNC_SNP_RESP_TO_LOCAL_HOME.S_STATE     | Number of snoop responses to the local home that L3 has the referenced line cached in the S state.                                                                                                                                        |         |
| 06H        | 04H         | UNC_SNP_RESP_TO_LOCAL_HOME.FWD_S_STATE | Number of responses to code or data read snoops to the local home that the L3 has the referenced cache line in the E state. The L3 cache line state is changed to the S state and the line is forwarded to the local home in the S state. |         |

## PERFORMANCE-MONITORING EVENTS

**Table A-5. Non-Architectural Performance Events In the Processor Uncore for Intel Core i7 Processor and Intel Xeon Processor 5500 Series**

| Event Num. | Umask Value | Event Mask Mnemonic                     | Description                                                                                                                                                                                                                               | Comment |
|------------|-------------|-----------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------|
| 06H        | 08H         | UNC_SNP_RESP_TO_LOCAL_HOME.FWD_I_STATE  | Number of responses to read invalidate snoops to the local home that the L3 has the referenced cache line in the M state. The L3 cache line state is invalidated and the line is forwarded to the local home in the M state.              |         |
| 06H        | 10H         | UNC_SNP_RESP_TO_LOCAL_HOME.CONFLICT     | Number of conflict snoop responses sent to the local home.                                                                                                                                                                                |         |
| 06H        | 20H         | UNC_SNP_RESP_TO_LOCAL_HOME.WB           | Number of responses to code or data read snoops to the local home that the L3 has the referenced line cached in the M state.                                                                                                              |         |
| 07H        | 01H         | UNC_SNP_RESP_TO_REMOTE_HOME.I_STATE     | Number of snoop responses to a remote home that L3 does not have the referenced cache line.                                                                                                                                               |         |
| 07H        | 02H         | UNC_SNP_RESP_TO_REMOTE_HOME.S_STATE     | Number of snoop responses to a remote home that L3 has the referenced line cached in the S state.                                                                                                                                         |         |
| 07H        | 04H         | UNC_SNP_RESP_TO_REMOTE_HOME.FWD_S_STATE | Number of responses to code or data read snoops to a remote home that the L3 has the referenced cache line in the E state. The L3 cache line state is changed to the S state and the line is forwarded to the remote home in the S state. |         |
| 07H        | 08H         | UNC_SNP_RESP_TO_REMOTE_HOME.FWD_I_STATE | Number of responses to read invalidate snoops to a remote home that the L3 has the referenced cache line in the M state. The L3 cache line state is invalidated and the line is forwarded to the remote home in the M state.              |         |
| 07H        | 10H         | UNC_SNP_RESP_TO_REMOTE_HOME.CONFLICT    | Number of conflict snoop responses sent to the local home.                                                                                                                                                                                |         |

**Table A-5. Non-Architectural Performance Events In the Processor Uncore for Intel Core i7 Processor and Intel Xeon Processor 5500 Series**

| Event Num. | Umask Value | Event Mask Mnemonic              | Description                                                                                                                                                                                                   | Comment |
|------------|-------------|----------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------|
| 07H        | 20H         | UNC_SNP_RESP_TO_REMOTE_HOME.WB   | Number of responses to code or data read snoops to a remote home that the L3 has the referenced line cached in the M state.                                                                                   |         |
| 07H        | 24H         | UNC_SNP_RESP_TO_REMOTE_HOME.HITM | Number of HITM snoop responses to a remote home                                                                                                                                                               |         |
| 08H        | 01H         | UNC_L3_HITS.READ                 | Number of code read, data read and RFO requests that hit in the L3                                                                                                                                            |         |
| 08H        | 02H         | UNC_L3_HITS.WRITE                | Number of writeback requests that hit in the L3. Writebacks from the cores will always result in L3 hits due to the inclusive property of the L3.                                                             |         |
| 08H        | 04H         | UNC_L3_HITS.PROBE                | Number of snoops from IOH or remote sockets that hit in the L3.                                                                                                                                               |         |
| 08H        | 03H         | UNC_L3_HITS.ANY                  | Number of reads and writes that hit the L3.                                                                                                                                                                   |         |
| 09H        | 01H         | UNC_L3_MISS.READ                 | Number of code read, data read and RFO requests that miss the L3.                                                                                                                                             |         |
| 09H        | 02H         | UNC_L3_MISS.WRITE                | Number of writeback requests that miss the L3. Should always be zero as writebacks from the cores will always result in L3 hits due to the inclusive property of the L3.                                      |         |
| 09H        | 04H         | UNC_L3_MISS.PROBE                | Number of snoops from IOH or remote sockets that miss the L3.                                                                                                                                                 |         |
| 09H        | 03H         | UNC_L3_MISS.ANY                  | Number of reads and writes that miss the L3.                                                                                                                                                                  |         |
| 0AH        | 01H         | UNC_L3_LINES_IN.M_STATE          | Counts the number of L3 lines allocated in M state. The only time a cache line is allocated in the M state is when the line was forwarded in M state is forwarded due to a Snoop Read Invalidate Own request. |         |
| 0AH        | 02H         | UNC_L3_LINES_IN.E_STATE          | Counts the number of L3 lines allocated in E state.                                                                                                                                                           |         |
| 0AH        | 04H         | UNC_L3_LINES_IN.S_STATE          | Counts the number of L3 lines allocated in S state.                                                                                                                                                           |         |

## PERFORMANCE-MONITORING EVENTS

**Table A-5. Non-Architectural Performance Events In the Processor Uncore for Intel Core i7 Processor and Intel Xeon Processor 5500 Series**

| Event Num. | Umask Value | Event Mask Mnemonic             | Description                                                                                                                                                                                   | Comment |
|------------|-------------|---------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------|
| 0AH        | 08H         | UNC_L3_LINES_IN.F_STATE         | Counts the number of L3 lines allocated in F state.                                                                                                                                           |         |
| 0AH        | 0FH         | UNC_L3_LINES_IN.ANY             | Counts the number of L3 lines allocated in any state.                                                                                                                                         |         |
| 0BH        | 01H         | UNC_L3_LINES_OUT.M_STATE        | Counts the number of L3 lines victimized that were in the M state. When the victim cache line is in M state, the line is written to its home cache agent which can be either local or remote. |         |
| 0BH        | 02H         | UNC_L3_LINES_OUT.E_STATE        | Counts the number of L3 lines victimized that were in the E state.                                                                                                                            |         |
| 0BH        | 04H         | UNC_L3_LINES_OUT.S_STATE        | Counts the number of L3 lines victimized that were in the S state.                                                                                                                            |         |
| 0BH        | 08H         | UNC_L3_LINES_OUT.I_STATE        | Counts the number of L3 lines victimized that were in the I state.                                                                                                                            |         |
| 0BH        | 10H         | UNC_L3_LINES_OUT.F_STATE        | Counts the number of L3 lines victimized that were in the F state.                                                                                                                            |         |
| 0BH        | 1FH         | UNC_L3_LINES_OUT.ANY            | Counts the number of L3 lines victimized in any state.                                                                                                                                        |         |
| 20H        | 01H         | UNC_QHL_REQUEST.S.IOH_READS     | Counts number of Quickpath Home Logic read requests from the IOH.                                                                                                                             |         |
| 20H        | 02H         | UNC_QHL_REQUEST.S.IOH_WRITES    | Counts number of Quickpath Home Logic write requests from the IOH.                                                                                                                            |         |
| 20H        | 04H         | UNC_QHL_REQUEST.S.REMOTE_READS  | Counts number of Quickpath Home Logic read requests from a remote socket.                                                                                                                     |         |
| 20H        | 08H         | UNC_QHL_REQUEST.S.REMOTE_WRITES | Counts number of Quickpath Home Logic write requests from a remote socket.                                                                                                                    |         |
| 20H        | 10H         | UNC_QHL_REQUEST.S.LOCAL_READS   | Counts number of Quickpath Home Logic read requests from the local socket.                                                                                                                    |         |
| 20H        | 20H         | UNC_QHL_REQUEST.S.LOCAL_WRITES  | Counts number of Quickpath Home Logic write requests from the local socket.                                                                                                                   |         |

**Table A-5. Non-Architectural Performance Events In the Processor Uncore for Intel Core i7 Processor and Intel Xeon Processor 5500 Series**

| Event Num. | Umask Value | Event Mask Mnemonic              | Description                                                                                                                                                                                                                                                            | Comment |
|------------|-------------|----------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------|
| 21H        | 01H         | UNC_QHL_CYCLES_FULL.IOH          | Counts uclk cycles all entries in the Quickpath Home Logic IOH are full.                                                                                                                                                                                               |         |
| 21H        | 02H         | UNC_QHL_CYCLES_FULL.REMOTE       | Counts uclk cycles all entries in the Quickpath Home Logic remote tracker are full.                                                                                                                                                                                    |         |
| 21H        | 04H         | UNC_QHL_CYCLES_FULL.LOCAL        | Counts uclk cycles all entries in the Quickpath Home Logic local tracker are full.                                                                                                                                                                                     |         |
| 22H        | 01H         | UNC_QHL_CYCLES_NO_T_EMPTY.IOH    | Counts uclk cycles all entries in the Quickpath Home Logic IOH is busy.                                                                                                                                                                                                |         |
| 22H        | 02H         | UNC_QHL_CYCLES_NO_T_EMPTY.REMOTE | Counts uclk cycles all entries in the Quickpath Home Logic remote tracker is busy.                                                                                                                                                                                     |         |
| 22H        | 04H         | UNC_QHL_CYCLES_NO_T_EMPTY.LOCAL  | Counts uclk cycles all entries in the Quickpath Home Logic local tracker is busy.                                                                                                                                                                                      |         |
| 23H        | 01H         | UNC_QHL_OCCUPANCY.IOH            | QHL IOH tracker allocate to deallocate read occupancy.                                                                                                                                                                                                                 |         |
| 23H        | 02H         | UNC_QHL_OCCUPANCY.REMOTE         | QHL remote tracker allocate to deallocate read occupancy.                                                                                                                                                                                                              |         |
| 23H        | 04H         | UNC_QHL_OCCUPANCY.LOCAL          | QHL local tracker allocate to deallocate read occupancy.                                                                                                                                                                                                               |         |
| 24H        | 02H         | UNC_QHL_ADDRESS_CONFLICTS.2WAY   | Counts number of QHL Active Address Table (AAT) entries that saw a max of 2 conflicts. The AAT is a structure that tracks requests that are in conflict. The requests themselves are in the home tracker entries. The count is reported when an AAT entry deallocated. |         |
| 24H        | 04H         | UNC_QHL_ADDRESS_CONFLICTS.3WAY   | Counts number of QHL Active Address Table (AAT) entries that saw a max of 3 conflicts. The AAT is a structure that tracks requests that are in conflict. The requests themselves are in the home tracker entries. The count is reported when an AAT entry deallocated. |         |

## PERFORMANCE-MONITORING EVENTS

**Table A-5. Non-Architectural Performance Events In the Processor Uncore for Intel Core i7 Processor and Intel Xeon Processor 5500 Series**

| Event Num. | Umask Value | Event Mask Mnemonic            | Description                                                                                                                                                                                     | Comment |
|------------|-------------|--------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------|
| 25H        | 01H         | UNC_QHL_CONFLICT_CYCLES.IOH    | Counts cycles the Quickpath Home Logic IOH Tracker contains two or more requests with an address conflict. A max of 3 requests can be in conflict.                                              |         |
| 25H        | 02H         | UNC_QHL_CONFLICT_CYCLES.REMOTE | Counts cycles the Quickpath Home Logic Remote Tracker contains two or more requests with an address conflict. A max of 3 requests can be in conflict.                                           |         |
| 25H        | 04H         | UNC_QHL_CONFLICT_CYCLES.LOCAL  | Counts cycles the Quickpath Home Logic Local Tracker contains two or more requests with an address conflict. A max of 3 requests can be in conflict.                                            |         |
| 26H        | 01H         | UNC_QHL_TO_QMC_BYPASS          | Counts number of requests to the Quickpath Memory Controller that bypass the Quickpath Home Logic. All local accesses can be bypassed. For remote requests, only read requests can be bypassed. |         |
| 27H        | 01H         | UNC_QMC_NORMAL_FULL.READ.CHO   | Uncore cycles all the entries in the DRAM channel 0 medium or low priority queue are occupied with read requests.                                                                               |         |
| 27H        | 02H         | UNC_QMC_NORMAL_FULL.READ.CH1   | Uncore cycles all the entries in the DRAM channel 1 medium or low priority queue are occupied with read requests.                                                                               |         |
| 27H        | 04H         | UNC_QMC_NORMAL_FULL.READ.CH2   | Uncore cycles all the entries in the DRAM channel 2 medium or low priority queue are occupied with read requests.                                                                               |         |
| 27H        | 08H         | UNC_QMC_NORMAL_FULL.WRITE.CHO  | Uncore cycles all the entries in the DRAM channel 0 medium or low priority queue are occupied with write requests.                                                                              |         |

## PERFORMANCE-MONITORING EVENTS

**Table A-5. Non-Architectural Performance Events In the Processor Uncore for Intel Core i7 Processor and Intel Xeon Processor 5500 Series**

| Event Num. | Umask Value | Event Mask Mnemonic           | Description                                                                                                           | Comment |
|------------|-------------|-------------------------------|-----------------------------------------------------------------------------------------------------------------------|---------|
| 27H        | 10H         | UNC_QMC_NORMAL_FULL.WRITE.CH1 | Counts cycles all the entries in the DRAM channel 1 medium or low priority queue are occupied with write requests.    |         |
| 27H        | 20H         | UNC_QMC_NORMAL_FULL.WRITE.CH2 | Uncore cycles all the entries in the DRAM channel 2 medium or low priority queue are occupied with write requests.    |         |
| 28H        | 01H         | UNC_QMC_ISOC_FULL.READ.CHO    | Counts cycles all the entries in the DRAM channel 0 high priority queue are occupied with isochronous read requests.  |         |
| 28H        | 02H         | UNC_QMC_ISOC_FULL.READ.CH1    | Counts cycles all the entries in the DRAM channel 1 high priority queue are occupied with isochronous read requests.  |         |
| 28H        | 04H         | UNC_QMC_ISOC_FULL.READ.CH2    | Counts cycles all the entries in the DRAM channel 2 high priority queue are occupied with isochronous read requests.  |         |
| 28H        | 08H         | UNC_QMC_ISOC_FULL.WRITE.CHO   | Counts cycles all the entries in the DRAM channel 0 high priority queue are occupied with isochronous write requests. |         |
| 28H        | 10H         | UNC_QMC_ISOC_FULL.WRITE.CH1   | Counts cycles all the entries in the DRAM channel 1 high priority queue are occupied with isochronous write requests. |         |
| 28H        | 20H         | UNC_QMC_ISOC_FULL.WRITE.CH2   | Counts cycles all the entries in the DRAM channel 2 high priority queue are occupied with isochronous write requests. |         |
| 29H        | 01H         | UNC_QMC_BUSY.READ.CHO         | Counts cycles where Quickpath Memory Controller has at least 1 outstanding read request to DRAM channel 0.            |         |

## PERFORMANCE-MONITORING EVENTS

**Table A-5. Non-Architectural Performance Events In the Processor Uncore for Intel Core i7 Processor and Intel Xeon Processor 5500 Series**

| Event Num. | Umask Value | Event Mask Mnemonic         | Description                                                                                                 | Comment |
|------------|-------------|-----------------------------|-------------------------------------------------------------------------------------------------------------|---------|
| 29H        | 02H         | UNC_QMC_BUSY.REA.D.CH1      | Counts cycles where Quickpath Memory Controller has at least 1 outstanding read request to DRAM channel 1.  |         |
| 29H        | 04H         | UNC_QMC_BUSY.REA.D.CH2      | Counts cycles where Quickpath Memory Controller has at least 1 outstanding read request to DRAM channel 2.  |         |
| 29H        | 08H         | UNC_QMC_BUSY.WRI.TE.CH0     | Counts cycles where Quickpath Memory Controller has at least 1 outstanding write request to DRAM channel 0. |         |
| 29H        | 10H         | UNC_QMC_BUSY.WRI.TE.CH1     | Counts cycles where Quickpath Memory Controller has at least 1 outstanding write request to DRAM channel 1. |         |
| 29H        | 20H         | UNC_QMC_BUSY.WRI.TE.CH2     | Counts cycles where Quickpath Memory Controller has at least 1 outstanding write request to DRAM channel 2. |         |
| 2AH        | 01H         | UNC_QMC_OCCUPANCY.CH0       | IMC channel 0 normal read request occupancy.                                                                |         |

|------------|-------------|-------------------------------------|---------------------------------------------------------------------------------------------------------|---------|
| 2EH        | 01H         | UNC_QMC_CRITICAL_PRIORITY_READS.CH0 | Counts the number of Quickpath Memory Controller channel 0 critical priority isochronous read requests. |         |
| 2EH        | 02H         | UNC_QMC_CRITICAL_PRIORITY_READS.CH1 | Counts the number of Quickpath Memory Controller channel 1 critical priority isochronous read requests. |         |
| 2EH        | 04H         | UNC_QMC_CRITICAL_PRIORITY_READS.CH2 | Counts the number of Quickpath Memory Controller channel 2 critical priority isochronous read requests. |         |
| 2EH        | 07H         | UNC_QMC_CRITICAL_PRIORITY_READS.ANY | Counts the number of Quickpath Memory Controller critical priority isochronous read requests.           |         |
| 2FH        | 01H         | UNC_QMC_WRITES.FULL.CH0             | Counts number of full cache line writes to DRAM channel 0.                                              |         |
| 2FH        | 02H         | UNC_QMC_WRITES.FULL.CH1             | Counts number of full cache line writes to DRAM channel 1.                                              |         |
| 2FH        | 04H         | UNC_QMC_WRITES.FULL.CH2             | Counts number of full cache line writes to DRAM channel 2.                                              |         |
| 2FH        | 07H         | UNC_QMC_WRITES.FULL.ANY             | Counts number of full cache line writes to DRAM.                                                        |         |
| 2FH        | 08H         | UNC_QMC_WRITES.PARTIAL.CH0          | Counts number of partial cache line writes to DRAM channel 0.                                           |         |
| 2FH        | 10H         | UNC_QMC_WRITES.PARTIAL.CH1          | Counts number of partial cache line writes to DRAM channel 1.                                           |         |
| 2FH        | 20H         | UNC_QMC_WRITES.PARTIAL.CH2          | Counts number of partial cache line writes to DRAM channel 2.                                           |         |
| 2FH        | 38H         | UNC_QMC_WRITES.PARTIAL.ANY          | Counts number of partial cache line writes to DRAM.                                                     |         |
| 30H        | 01H         | UNC_QMC_CANCEL.CH0                  | Counts number of DRAM channel 0 cancel requests.                                                        |         |
| 30H        | 02H         | UNC_QMC_CANCEL.CH1                  | Counts number of DRAM channel 1 cancel requests.                                                        |         |
| 30H        | 04H         | UNC_QMC_CANCEL.CH2                  | Counts number of DRAM channel 2 cancel requests.                                                        |         |
| 30H        | 07H         | UNC_QMC_CANCEL.ANY                  | Counts number of DRAM cancel requests.                                                                  |         |

**Table A-5. Non-Architectural Performance Events In the Processor Uncore for Intel Core i7 Processor and Intel Xeon Processor 5500 Series**

| Event Num. | Umask Value | Event Mask Mnemonic          | Description                                                                                                                                                                                                                                                                                                                 | Comment |
|------------|-------------|------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------|
| 31H        | 01H         | UNC_QMC_PRIORITY_UPDATES.CHO | Counts number of DRAM channel 0 priority updates. A priority update occurs when an ISOC high or critical request is received by the QHL and there is a matching request with normal priority that has already been issued to the QMC. In this instance, the QHL will send a priority update to QMC to expedite the request. |         |
| 31H        | 02H         | UNC_QMC_PRIORITY_UPDATES.CH1 | Counts number of DRAM channel 1 priority updates. A priority update occurs when an ISOC high or critical request is received by the QHL and there is a matching request with normal priority that has already been issued to the QMC. In this instance, the QHL will send a priority update to QMC to expedite the request. |         |
| 31H        | 04H         | UNC_QMC_PRIORITY_UPDATES.CH2 | Counts number of DRAM channel 2 priority updates. A priority update occurs when an ISOC high or critical request is received by the QHL and there is a matching request with normal priority that has already been issued to the QMC. In this instance, the QHL will send a priority update to QMC to expedite the request. |         |
| 31H        | 07H         | UNC_QMC_PRIORITY_UPDATES.ANY | Counts number of DRAM priority updates. A priority update occurs when an ISOC high or critical request is received by the QHL and there is a matching request with normal priority that has already been issued to the QMC. In this instance, the QHL will send a priority update to QMC to expedite the request.           |         |
| 33H        | 04H         | UNC_QHL_FRC_ACK_CNFLTS.LOCAL | Counts number of Force Acknowledge Conflict messages sent by the Quickpath Home Logic to the local home.                                                                                                                                                                                                                    |         |

## PERFORMANCE-MONITORING EVENTS

**Table A-5. Non-Architectural Performance Events In the Processor Uncore for Intel Core i7 Processor and Intel Xeon Processor 5500 Series**

| Event Num. | Umask Value | Event Mask Mnemonic                             | Description                                                                                                                                                                                                                                                                            | Comment |
|------------|-------------|-------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------|
| 40H        | 01H         | UNC_QPI_TX_STALL<br>ED_SINGLE_FLIT.HOME.LINK_0  | Counts cycles the Quickpath outbound link 0 HOME virtual channel is stalled due to lack of a VNA and VNO credit. Note that this event does not filter out when a flit would not have been selected for arbitration because another virtual channel is getting arbitrated.              |         |
| 40H        | 02H         | UNC_QPI_TX_STALL<br>ED_SINGLE_FLIT.SNOOP.LINK_0 | Counts cycles the Quickpath outbound link 0 SNOOP virtual channel is stalled due to lack of a VNA and VNO credit. Note that this event does not filter out when a flit would not have been selected for arbitration because another virtual channel is getting arbitrated.             |         |
| 40H        | 04H         | UNC_QPI_TX_STALL<br>ED_SINGLE_FLIT.NDR.LINK_0   | Counts cycles the Quickpath outbound link 0 non-data response virtual channel is stalled due to lack of a VNA and VNO credit. Note that this event does not filter out when a flit would not have been selected for arbitration because another virtual channel is getting arbitrated. |         |
| 40H        | 08H         | UNC_QPI_TX_STALL<br>ED_SINGLE_FLIT.HOME.LINK_1  | Counts cycles the Quickpath outbound link 1 HOME virtual channel is stalled due to lack of a VNA and VNO credit. Note that this event does not filter out when a flit would not have been selected for arbitration because another virtual channel is getting arbitrated.              |         |
| 40H        | 10H         | UNC_QPI_TX_STALL<br>ED_SINGLE_FLIT.SNOOP.LINK_1 | Counts cycles the Quickpath outbound link 1 SNOOP virtual channel is stalled due to lack of a VNA and VNO credit. Note that this event does not filter out when a flit would not have been selected for arbitration because another virtual channel is getting arbitrated.             |         |

**Table A-5. Non-Architectural Performance Events In the Processor Uncore for Intel Core i7 Processor and Intel Xeon Processor 5500 Series**

| Event Num. | Umask Value | Event Mask Mnemonic                               | Description                                                                                                                                                                                                                                                                             | Comment |
|------------|-------------|---------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------|
| 40H        | 20H         | UNC_QPI_TX_STALL<br>ED_SINGLE_FLIT.NDR<br>.LINK_1 | Counts cycles the Quickpath outbound link 1 non-data response virtual channel is stalled due to lack of a VNA and VNO credit. Note that this event does not filter out when a flit would not have been selected for arbitration because another virtual channel is getting arbitrated.  |         |
| 40H        | 07H         | UNC_QPI_TX_STALL<br>ED_SINGLE_FLIT.LIN<br>K_0     | Counts cycles the Quickpath outbound link 0 virtual channels are stalled due to lack of a VNA and VNO credit. Note that this event does not filter out when a flit would not have been selected for arbitration because another virtual channel is getting arbitrated.                  |         |
| 40H        | 38H         | UNC_QPI_TX_STALL<br>ED_SINGLE_FLIT.LIN<br>K_1     | Counts cycles the Quickpath outbound link 1 virtual channels are stalled due to lack of a VNA and VNO credit. Note that this event does not filter out when a flit would not have been selected for arbitration because another virtual channel is getting arbitrated.                  |         |
| 41H        | 01H         | UNC_QPI_TX_STALL<br>ED_MULTI_FLIT.DRS.<br>LINK_0  | Counts cycles the Quickpath outbound link 0 Data ResponSe virtual channel is stalled due to lack of VNA and VNO credits. Note that this event does not filter out when a flit would not have been selected for arbitration because another virtual channel is getting arbitrated.       |         |
| 41H        | 02H         | UNC_QPI_TX_STALL<br>ED_MULTI_FLIT.NCB.<br>LINK_0  | Counts cycles the Quickpath outbound link 0 Non-Coherent Bypass virtual channel is stalled due to lack of VNA and VNO credits. Note that this event does not filter out when a flit would not have been selected for arbitration because another virtual channel is getting arbitrated. |         |

## PERFORMANCE-MONITORING EVENTS

To read or write data, the referenced DRAM page must first be opened.                                                                                                                  |         |

## PERFORMANCE-MONITORING EVENTS

**Table A-5. Non-Architectural Performance Events In the Processor Uncore for Intel Core i7 Processor and Intel Xeon Processor 5500 Series**

| Event Num. | Umask Value | Event Mask Mnemonic     | Description                                                                                                                                                                                                                                                                                                                       | Comment |
|------------|-------------|-------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------|
| 60H        | 04H         | UNC_DRAM_OPEN.CH2       | Counts number of DRAM Channel 2 open commands issued either for read or write. To read or write data, the referenced DRAM page must first be opened.                                                                                                                                                                              |         |
| 61H        | 01H         | UNC_DRAM_PAGE_CLOSE.CHO | DRAM channel 0 command issued to CLOSE a page due to page idle timer expiration. Closing a page is done by issuing a precharge.                                                                                                                                                                                                   |         |
| 61H        | 02H         | UNC_DRAM_PAGE_CLOSE.CH1 | DRAM channel 1 command issued to CLOSE a page due to page idle timer expiration. Closing a page is done by issuing a precharge.                                                                                                                                                                                                   |         |
| 61H        | 04H         | UNC_DRAM_PAGE_CLOSE.CH2 | DRAM channel 2 command issued to CLOSE a page due to page idle timer expiration. Closing a page is done by issuing a precharge.                                                                                                                                                                                                   |         |
| 62H        | 01H         | UNC_DRAM_PAGE_MISS.CHO  | Counts the number of precharges (PRE) that were issued to DRAM channel 0 because there was a page miss. A page miss refers to a situation in which a page is currently open and another page from the same bank needs to be opened. The new page experiences a page miss. Closing of the old page is done by issuing a precharge. |         |
| 62H        | 02H         | UNC_DRAM_PAGE_MISS.CH1  | Counts the number of precharges (PRE) that were issued to DRAM channel 1 because there was a page miss. A page miss refers to a situation in which a page is currently open and another page from the same bank needs to be opened. The new page experiences a page miss. Closing of the old page is done by issuing a precharge. |         |

**Table A-5. Non-Architectural Performance Events In the Processor Uncore for Intel Core i7 Processor and Intel Xeon Processor 5500 Series**

| Event Num. | Umask Value | Event Mask Mnemonic               | Description                                                                                                                                                                                                                                                                                                                       | Comment |
|------------|-------------|-----------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------|
| 62H        | 04H         | UNC_DRAM_PAGE_M<br>ISS.CH2        | Counts the number of precharges (PRE) that were issued to DRAM channel 2 because there was a page miss. A page miss refers to a situation in which a page is currently open and another page from the same bank needs to be opened. The new page experiences a page miss. Closing of the old page is done by issuing a precharge. |         |
| 63H        | 01H         | UNC_DRAM_READ_C<br>AS.CH0         | Counts the number of times a read CAS command was issued on DRAM channel 0.                                                                                                                                                                                                                                                       |         |
| 63H        | 02H         | UNC_DRAM_READ_C<br>AS.AUTOPRE_CHO | Counts the number of times a read CAS command was issued on DRAM channel 0 where the command issued used the auto-precharge (auto page close) mode.                                                                                                                                                                               |         |
| 63H        | 04H         | UNC_DRAM_READ_C<br>AS.CH1         | Counts the number of times a read CAS command was issued on DRAM channel 1.                                                                                                                                                                                                                                                       |         |
| 63H        | 08H         | UNC_DRAM_READ_C<br>AS.AUTOPRE_CH1 | Counts the number of times a read CAS command was issued on DRAM channel 1 where the command issued used the auto-precharge (auto page close) mode.                                                                                                                                                                               |         |
| 63H        | 10H         | UNC_DRAM_READ_C<br>AS.CH2         | Counts the number of times a read CAS command was issued on DRAM channel 2.                                                                                                                                                                                                                                                       |         |
| 63H        | 20H         | UNC_DRAM_READ_C<br>AS.AUTOPRE_CH2 | Counts the number of times a read CAS command was issued on DRAM channel 2 where the command issued used the auto-precharge (auto page close) mode.                                                                                                                                                                               |         |
| 64H        | 01H         | UNC_DRAM_WRITE_C<br>AS.CH0        | Counts the number of times a write CAS command was issued on DRAM channel 0.                                                                                                                                                                                                                                                      |         |

## PERFORMANCE-MONITORING EVENTS

**Table A-5. Non-Architectural Performance Events In the Processor Uncore for Intel Core i7 Processor and Intel Xeon Processor 5500 Series**

| Event Num. | Umask Value | Event Mask Mnemonic            | Description                                                                                                                                                                    | Comment |
|------------|-------------|--------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------|
| 64H        | 02H         | UNC_DRAM_WRITE_CAS.AUTOPRE_CHO | Counts the number of times a write CAS command was issued on DRAM channel 0 where the command issued used the auto-precharge (auto page close) mode.                           |         |
| 64H        | 04H         | UNC_DRAM_WRITE_CAS.CH1         | Counts the number of times a write CAS command was issued on DRAM channel 1.                                                                                                   |         |
| 64H        | 08H         | UNC_DRAM_WRITE_CAS.AUTOPRE_CH1 | Counts the number of times a write CAS command was issued on DRAM channel 1 where the command issued used the auto-precharge (auto page close) mode.                           |         |
| 64H        | 10H         | UNC_DRAM_WRITE_CAS.CH2         | Counts the number of times a write CAS command was issued on DRAM channel 2.                                                                                                   |         |
| 64H        | 20H         | UNC_DRAM_WRITE_CAS.AUTOPRE_CH2 | Counts the number of times a write CAS command was issued on DRAM channel 2 where the command issued used the auto-precharge (auto page close) mode.                           |         |
| 65H        | 01H         | UNC_DRAM_REFRESH.CHO           | Counts number of DRAM channel 0 refresh commands. DRAM loses data content over time. In order to keep correct data content, the data values have to be refreshed periodically. |         |
| 65H        | 02H         | UNC_DRAM_REFRESH.CH1           | Counts number of DRAM channel 1 refresh commands. DRAM loses data content over time. In order to keep correct data content, the data values have to be refreshed periodically. |         |
| 65H        | 04H         | UNC_DRAM_REFRESH.CH2           | Counts number of DRAM channel 2 refresh commands. DRAM loses data content over time. In order to keep correct data content, the data values have to be refreshed periodically. |         |

**Table A-5. Non-Architectural Performance Events In the Processor Uncore for Intel Core i7 Processor and Intel Xeon Processor 5500 Series**

| Event Num. | Umask Value | Event Mask Mnemonic   | Description                                                                                                                                                                                      | Comment |
|------------|-------------|-----------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------|
| 66H        | 01H         | UNC_DRAM_PRE_AL_L.CH0 | Counts number of DRAM Channel 0 precharge-all (PREALL) commands that close all open pages in a rank. PREALL is issued when the DRAM needs to be refreshed or needs to go into a power down mode. |         |
| 66H        | 02H         | UNC_DRAM_PRE_AL_L.CH1 | Counts number of DRAM Channel 1 precharge-all (PREALL) commands that close all open pages in a rank. PREALL is issued when the DRAM needs to be refreshed or needs to go into a power down mode. |         |
| 66H        | 04H         | UNC_DRAM_PRE_AL_L.CH2 | Counts number of DRAM Channel 2 precharge-all (PREALL) commands that close all open pages in a rank. PREALL is issued when the DRAM needs to be refreshed or needs to go into a power down mode. |         |

Intel Xeon processors with CPUID signature of DisplayFamily\_DisplayModel 06\_2EH have a distinct uncore sub-system that is significantly different from the uncore found in processors with CPUID signature 06\_1AH, 06\_1EH, and 06\_1FH. Non-architectural Performance monitoring events for its uncore will be available in future documentation.

## A.4 PERFORMANCE MONITORING EVENTS FOR PROCESSORS BASED ON INTEL® MICROARCHITECTURE CODE NAME WESTMERE

Intel 64 processors based on Intel® microarchitecture code name Westmere support the architectural and non-architectural performance-monitoring events listed in Table A-1 and Table A-6. Table A-6 applies to processors with CPUID signature of DisplayFamily\_DisplayModel encoding with the following values: 06\_25H, 06\_2CH. In addition, these processors (CPUID signature of DisplayFamily\_DisplayModel 06\_25H, 06\_2CH) also support the following non-architectural, product-specific uncore performance-monitoring events listed in Table A-7. Fixed counters support the architecture events defined in Table A-9.

## PERFORMANCE-MONITORING EVENTS

**Table A-6. Non-Architectural Performance Events In the Processor Core for Processors Based on Intel Microarchitecture Code Name Westmere**

| Event Num. | Umask Value | Event Mask Mnemonic             | Description                                                                                                                                                                                                                                                                                                                                           | Comment |
|------------|-------------|---------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------|
| 03H        | 02H         | LOAD_BLOCK.OVERLAP_STORE        | Loads that partially overlap an earlier store.                                                                                                                                                                                                                                                                                                        |         |
| 04H        | 07H         | SB_DRAIN.ANY                    | All Store buffer stall cycles.                                                                                                                                                                                                                                                                                                                        |         |
| 05H        | 02H         | MISALIGN_MEMORY.STORE           | All store referenced with misaligned address.                                                                                                                                                                                                                                                                                                         |         |
| 06H        | 04H         | STORE_BLOCKS.AT_RET             | Counts number of loads delayed with at-Retirement block code. The following loads need to be executed at retirement and wait for all senior stores on the same thread to be drained: load splitting across 4K boundary (page split), load accessing uncacheable (UC or USWC) memory, load lock, and load with page table in UC or USWC memory region. |         |
| 06H        | 08H         | STORE_BLOCKS.L1D_BLOCK          | Cacheable loads delayed with L1D block code.                                                                                                                                                                                                                                                                                                          |         |
| 07H        | 01H         | PARTIAL_ADDRESS_ALIAS           | Counts false dependency due to partial address aliasing.                                                                                                                                                                                                                                                                                              |         |
| 08H        | 01H         | DTLB_LOAD_MISSES.ANY            | Counts all load misses that cause a page walk.                                                                                                                                                                                                                                                                                                        |         |
| 08H        | 02H         | DTLB_LOAD_MISSES.WALK_COMPLETED | Counts number of completed page walks due to load miss in the STLB.                                                                                                                                                                                                                                                                                   |         |
| 08H        | 04H         | DTLB_LOAD_MISSES.WALK_CYCLES    | Cycles PMH is busy with a page walk due to a load miss in the STLB.                                                                                                                                                                                                                                                                                   |         |
| 08H        | 10H         | DTLB_LOAD_MISSES.STLB_HIT       | Number of cache load STLB hits.                                                                                                                                                                                                                                                                                                                       |         |
| 08H        | 20H         | DTLB_LOAD_MISSES.PDE_MISS       | Number of DTLB cache load misses where the low part of the linear to physical address translation was missed.                                                                                                                                                                                                                                         |         |
| 0BH        | 01H         | MEM_INST_RETIRED.LOADS          | Counts the number of instructions with an architecturally-visible load retired on the architected path.                                                                                                                                                                                                                                               |         |
| 0BH        | 02H         | MEM_INST_RETIRED.STORES         | Counts the number of instructions with an architecturally-visible store retired on the architected path.                                                                                                                                                                                                                                              |         |

**Table A-6. Non-Architectural Performance Events In the Processor Core for Processors Based on Intel Microarchitecture Code Name Westmere**

| Event Num. | Umask Value | Event Mask Mnemonic                                | Description                                                                                                                                                                                                               | Comment                             |
|------------|-------------|----------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------|
| OBH        | 10H         | MEM_INST_RETIRED.LATENCY_ABOVE_THRESHOLD           | Counts the number of instructions exceeding the latency specified with Id_lat facility.                                                                                                                                   | In conjunction with Id_lat facility |
| OCH        | 01H         | MEM_STORE_RETIRE.D.DTLB_MISS                       | The event counts the number of retired stores that missed the DTLB. The DTLB miss is not counted if the store operation causes a fault. Does not counter prefetches. Counts both primary and secondary misses to the TLB. |                                     |
| OEH        | 01H         | UOPS_ISSUED.ANY                                    | Counts the number of Uops issued by the Register Allocation Table to the Reservation Station, i.e. the UOPs issued from the front end to the back end.                                                                    |                                     |
| OEH        | 01H         | UOPS_ISSUEDSTALL.ED_CYCLES                         | Counts the number of cycles no Uops issued by the Register Allocation Table to the Reservation Station, i.e. the UOPs issued from the front end to the back end.                                                          | set "invert=1, cmask = 1"           |
| OEH        | 02H         | UOPS_ISSUED.FUSED                                  | Counts the number of fused Uops that were issued from the Register Allocation Table to the Reservation Station.                                                                                                           |                                     |
| OFH        | 01H         | MEM_UNCORE_RETIRED.UNKNOWN_SOURCE                  | Load instructions retired with unknown LLC miss (Precise Event).                                                                                                                                                          | Applicable to one and two sockets   |
| OFH        | 02H         | MEM_UNCORE_RETIRED.OHTER_CORE_L2_HIT               | Load instructions retired that HIT modified data in sibling core (Precise Event).                                                                                                                                         | Applicable to one and two sockets   |
| OFH        | 04H         | MEM_UNCORE_RETIRED.REMOTE_HITM                     | Load instructions retired that HIT modified data in remote socket (Precise Event).                                                                                                                                        | Applicable to two sockets only      |
| OFH        | 08H         | MEM_UNCORE_RETIRED.LOCAL_DRAM_AND_REMOTE_CACHE_HIT | Load instructions retired local dram and remote cache HIT data sources (Precise Event).                                                                                                                                   | Applicable to one and two sockets   |

## PERFORMANCE-MONITORING EVENTS

**Table A-6. Non-Architectural Performance Events In the Processor Core for Processors Based on Intel Microarchitecture Code Name Westmere**

| Event Num. | Umask Value | Event Mask Mnemonic                          | Description                                                                                                                                                                                                                                                                               | Comment                           |
|------------|-------------|----------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------|
| OFH        | 10H         | MEM_UNCORE_RETI<br>RED.REMOTE_DRAM           | Load instructions retired remote DRAM and remote home-remote cache HITM (Precise Event).                                                                                                                                                                                                  | Applicable to two sockets only    |
| OFH        | 20H         | MEM_UNCORE_RETI<br>RED.OTHER_LLC_MIS<br>S    | Load instructions retired other LLC miss (Precise Event).                                                                                                                                                                                                                                 | Applicable to two sockets only    |
| OFH        | 80H         | MEM_UNCORE_RETI<br>RED.UNCACHEABLE           | Load instructions retired I/O (Precise Event).                                                                                                                                                                                                                                            | Applicable to one and two sockets |
| 10H        | 01H         | FP_COMP_OPS_EXE.<br>X87                      | Counts the number of FP Computational Uops Executed. The number of FADD, FSUB, FCOM, FMULs, integer MULs and IMULs, FDIVs, FPREMs, FSQRTs, integer DIVs, and IDIVs. This event does not distinguish an FADD used in the middle of a transcendental flow from a separate FADD instruction. |                                   |
| 10H        | 02H         | FP_COMP_OPS_EXE.<br>MMX                      | Counts number of MMX Uops executed.                                                                                                                                                                                                                                                       |                                   |
| 10H        | 04H         | FP_COMP_OPS_EXE.<br>SSE_FPS                  | Counts number of SSE and SSE2 FP uops executed.                                                                                                                                                                                                                                           |                                   |
| 10H        | 08H         | FP_COMP_OPS_EXE.<br>SSE2_INTEGER             | Counts number of SSE2 integer uops executed.                                                                                                                                                                                                                                              |                                   |
| 10H        | 10H         | FP_COMP_OPS_EXE.<br>SSE_FPS_PACKED           | Counts number of SSE FP packed uops executed.                                                                                                                                                                                                                                             |                                   |
| 10H        | 20H         | FP_COMP_OPS_EXE.<br>SSE_FPS_SCALAR           | Counts number of SSE FP scalar uops executed.                                                                                                                                                                                                                                             |                                   |

**Table A-6. Non-Architectural Performance Events In the Processor Core for Processors Based on Intel Microarchitecture Code Name Westmere**

| Event Num. | Umask Value | Event Mask Mnemonic          | Description                                                                                                                                                                                                                                                                            | Comment                               |
|------------|-------------|------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------|
| 12H        | 04H         | SIMD_INT_128.PACK            | Counts number of 128 bit SIMD integer pack operations.                                                                                                                                                                                                                                 |                                       |
| 12H        | 08H         | SIMD_INT_128.UNPACK          | Counts number of 128 bit SIMD integer unpack operations.                                                                                                                                                                                                                               |                                       |
| 12H        | 10H         | SIMD_INT_128.PACK ED_LOGICAL | Counts number of 128 bit SIMD integer logical operations.                                                                                                                                                                                                                              |                                       |
| 12H        | 20H         | SIMD_INT_128.PACK ED_ARITH   | Counts number of 128 bit SIMD integer arithmetic operations.                                                                                                                                                                                                                           |                                       |
| 12H        | 40H         | SIMD_INT_128.SHUFFLE_MOVE    | Counts number of 128 bit SIMD integer shuffle and move operations.                                                                                                                                                                                                                     |                                       |
| 13H        | 01H         | LOAD_DISPATCH.RS             | Counts number of loads dispatched from the Reservation Station that bypass the Memory Order Buffer.                                                                                                                                                                                    |                                       |
| 13H        | 02H         | LOAD_DISPATCH.RS_DELAYED     | Counts the number of delayed RS dispatches at the stage latch. If an RS dispatch can not bypass to LB, it has another chance to dispatch from the one-cycle delayed staging latch before it is written into the LB.                                                                    |                                       |
| 13H        | 04H         | LOAD_DISPATCH.MOB            | Counts the number of loads dispatched from the Reservation Station to the Memory Order Buffer.                                                                                                                                                                                         |                                       |
| 13H        | 07H         | LOAD_DISPATCH.ANY            | Counts all loads dispatched from the Reservation Station.                                                                                                                                                                                                                              |                                       |
| 14H        | 01H         | ARITH.CYCLES_DIV_BUSY        | Counts the number of cycles the divider is busy executing divide or square root operations. The divide can be integer, X87 or Streaming SIMD Extensions (SSE). The square root operation can be either X87 or SSE.<br>Set 'edge =1, invert=1, cmask=1' to count the number of divides. | Count may be incorrect When SMT is on |

## PERFORMANCE-MONITORING EVENTS

**Table A-6. Non-Architectural Performance Events In the Processor Core for Processors Based on Intel Microarchitecture Code Name Westmere**

| Event Num. | Umask Value | Event Mask Mnemonic      | Description                                                                                                                                                                                                                                                                                                                                                                                                                                           | Comment                                                                                                                        |
|------------|-------------|--------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------|
| 14H        | 02H         | ARITH.MUL                | Counts the number of multiply operations executed. This includes integer as well as floating point multiply operations but excludes DPPS mul and MPSAD.                                                                                                                                                                                                                                                                                               | Count may be incorrect When SMT is on                                                                                          |
| 17H        | 01H         | INST_QUEUE_WRITE S       | Counts the number of instructions written into the instruction queue every cycle.                                                                                                                                                                                                                                                                                                                                                                     |                                                                                                                                |
| 18H        | 01H         | INST_DECODED.DECO        | Counts number of instructions that require decoder 0 to be decoded. Usually, this means that the instruction maps to more than 1 uop.                                                                                                                                                                                                                                                                                                                 |                                                                                                                                |
| 19H        | 01H         | TWO_UOP_INSTS_D ECODED   | An instruction that generates two uops was decoded.                                                                                                                                                                                                                                                                                                                                                                                                   |                                                                                                                                |
| 1EH        | 01H         | INST_QUEUE_WRITE _CYCLES | This event counts the number of cycles during which instructions are written to the instruction queue. Dividing this counter by the number of instructions written to the instruction queue (INST_QUEUE_WRITE) yields the average number of instructions decoded each cycle. If this number is less than four and the pipe stalls, this indicates that the decoder is failing to decode enough instructions per cycle to sustain the 4-wide pipeline. | If SSE* instructions that are 6 bytes or longer arrive one after another, then front end throughput may limit execution speed. |
| 20H        | 01H         | LSD_OVERFLOW             | Number of loops that can not stream from the instruction queue.                                                                                                                                                                                                                                                                                                                                                                                       |                                                                                                                                |
| 24H        | 01H         | L2_RQSTS.LD_HIT          | Counts number of loads that hit the L2 cache. L2 loads include both L1D demand misses as well as L1D prefetches. L2 loads can be rejected for various reasons. Only non rejected loads are counted.                                                                                                                                                                                                                                                   |                                                                                                                                |

**Table A-6. Non-Architectural Performance Events In the Processor Core for Processors Based on Intel Microarchitecture Code Name Westmere**

| Event Num. | Umask Value | Event Mask Mnemonic  | Description                                                                                                                                                                                                                                                         | Comment |
|------------|-------------|----------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------|
| 24H        | 02H         | L2_RQSTS.LD_MISS     | Counts the number of loads that miss the L2 cache. L2 loads include both L1D demand misses as well as L1D prefetches.                                                                                                                                               |         |
| 24H        | 03H         | L2_RQSTS.LLOADS      | Counts all L2 load requests. L2 loads include both L1D demand misses as well as L1D prefetches.                                                                                                                                                                     |         |
| 24H        | 04H         | L2_RQSTS.RFO_HIT     | Counts the number of store RFO requests that hit the L2 cache. L2 RFO requests include both L1D demand RFO misses as well as L1D RFO prefetches. Count includes WC memory requests, where the data is not fetched but the permission to write the line is required. |         |
| 24H        | 08H         | L2_RQSTS.RFO_MISS    | Counts the number of store RFO requests that miss the L2 cache. L2 RFO requests include both L1D demand RFO misses as well as L1D RFO prefetches.                                                                                                                   |         |
| 24H        | 0CH         | L2_RQSTS.RFOS        | Counts all L2 store RFO requests. L2 RFO requests include both L1D demand RFO misses as well as L1D RFO prefetches..                                                                                                                                                |         |
| 24H        | 10H         | L2_RQSTS.IFETCH_HIT  | Counts number of instruction fetches that hit the L2 cache. L2 instruction fetches include both L1I demand misses as well as L1I instruction prefetches.                                                                                                            |         |
| 24H        | 20H         | L2_RQSTS.IFETCH_MISS | Counts number of instruction fetches that miss the L2 cache. L2 instruction fetches include both L1I demand misses as well as L1I instruction prefetches.                                                                                                           |         |
| 24H        | 30H         | L2_RQSTS.IFETCHES    | Counts all instruction fetches. L2 instruction fetches include both L1I demand misses as well as L1I instruction prefetches.                                                                                                                                        |         |

## PERFORMANCE-MONITORING EVENTS

**Table A-6. Non-Architectural Performance Events In the Processor Core for Processors Based on Intel Microarchitecture Code Name Westmere**

| Event Num. | Umask Value | Event Mask Mnemonic            | Description                                                                                                                                                                            | Comment |
|------------|-------------|--------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------|
| 24H        | 40H         | L2_RQSTS.PREFETC H_HIT         | Counts L2 prefetch hits for both code and data.                                                                                                                                        |         |
| 24H        | 80H         | L2_RQSTS.PREFETC H_MISS        | Counts L2 prefetch misses for both code and data.                                                                                                                                      |         |
| 24H        | COH         | L2_RQSTS.PREFETC HES           | Counts all L2 prefetches for both code and data.                                                                                                                                       |         |
| 24H        | AAH         | L2_RQSTS.MISS                  | Counts all L2 misses for both code and data.                                                                                                                                           |         |
| 24H        | FFH         | L2_RQSTS.REFEREN CES           | Counts all L2 requests for both code and data.                                                                                                                                         |         |
| 26H        | 01H         | L2_DATA_RQSTS.DEMAND.I_STATE   | Counts number of L2 data demand loads where the cache line to be loaded is in the I (invalid) state, i.e. a cache miss. L2 demand loads are both L1D demand misses and L1D prefetches. |         |
| 26H        | 02H         | L2_DATA_RQSTS.DEMAND.S_STATE   | Counts number of L2 data demand loads where the cache line to be loaded is in the S (shared) state. L2 demand loads are both L1D demand misses and L1D prefetches.                     |         |
| 26H        | 04H         | L2_DATA_RQSTS.DEMAND.E_STATE   | Counts number of L2 data demand loads where the cache line to be loaded is in the E (exclusive) state. L2 demand loads are both L1D demand misses and L1D prefetches.                  |         |
| 26H        | 08H         | L2_DATA_RQSTS.DEMAND.M_STATE   | Counts number of L2 data demand loads where the cache line to be loaded is in the M (modified) state. L2 demand loads are both L1D demand misses and L1D prefetches.                   |         |
| 26H        | 0FH         | L2_DATA_RQSTS.DEMAND.MESI      | Counts all L2 data demand requests. L2 demand loads are both L1D demand misses and L1D prefetches.                                                                                     |         |
| 26H        | 10H         | L2_DATA_RQSTS.PREFETCH.I_STATE | Counts number of L2 prefetch data loads where the cache line to be loaded is in the I (invalid) state, i.e. a cache miss.                                                              |         |

**Table A-6. Non-Architectural Performance Events In the Processor Core for Processors Based on Intel Microarchitecture Code Name Westmere**

| Event Num. | Umask Value | Event Mask Mnemonic            | Description                                                                                                                                                                                           | Comment                      |
|------------|-------------|--------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------|
| 26H        | 20H         | L2_DATA_RQSTS.PREFETCH.S_STATE | Counts number of L2 prefetch data loads where the cache line to be loaded is in the S (shared) state. A prefetch RFO will miss on an S state line, while a prefetch read will hit on an S state line. |                              |
| 26H        | 40H         | L2_DATA_RQSTS.PREFETCH.E_STATE | Counts number of L2 prefetch data loads where the cache line to be loaded is in the E (exclusive) state.                                                                                              |                              |
| 26H        | 80H         | L2_DATA_RQSTS.PREFETCH.M_STATE | Counts number of L2 prefetch data loads where the cache line to be loaded is in the M (modified) state.                                                                                               |                              |
| 26H        | FOH         | L2_DATA_RQSTS.PREFETCH.MESI    | Counts all L2 prefetch requests.                                                                                                                                                                      |                              |
| 26H        | FFH         | L2_DATA_RQSTS.ANY              | Counts all L2 data requests.                                                                                                                                                                          |                              |
| 27H        | 01H         | L2_WRITE.RFO.I_STATE           | Counts number of L2 demand store RFO requests where the cache line to be loaded is in the I (invalid) state, i.e, a cache miss. The L1D prefetcher does not issue a RFO prefetch.                     | This is a demand RFO request |
| 27H        | 02H         | L2_WRITE.RFO.S_STATE           | Counts number of L2 store RFO requests where the cache line to be loaded is in the S (shared) state. The L1D prefetcher does not issue a RFO prefetch.,.                                              | This is a demand RFO request |
| 27H        | 08H         | L2_WRITE.RFO.M_STATE           | Counts number of L2 store RFO requests where the cache line to be loaded is in the M (modified) state. The L1D prefetcher does not issue a RFO prefetch.                                              | This is a demand RFO request |
| 27H        | 0EH         | L2_WRITE.RFO.HIT               | Counts number of L2 store RFO requests where the cache line to be loaded is in either the S, E or M states. The L1D prefetcher does not issue a RFO prefetch.                                         | This is a demand RFO request |
| 27H        | 0FH         | L2_WRITE.RFO.MESI              | Counts all L2 store RFO requests.The L1D prefetcher does not issue a RFO prefetch.                                                                                                                    | This is a demand RFO request |

## PERFORMANCE-MONITORING EVENTS

**Table A-6. Non-Architectural Performance Events In the Processor Core for Processors Based on Intel Microarchitecture Code Name Westmere**

| Event Num. | Umask Value | Event Mask Mnemonic   | Description                                                                                                                    | Comment |
|------------|-------------|-----------------------|--------------------------------------------------------------------------------------------------------------------------------|---------|
| 27H        | 10H         | L2_WRITE.LOCK.I_STATE | Counts number of L2 demand lock RFO requests where the cache line to be loaded is in the I (invalid) state, i.e. a cache miss. |         |
| 27H        | 20H         | L2_WRITE.LOCK.S_STATE | Counts number of L2 lock RFO requests where the cache line to be loaded is in the S (shared) state.                            |         |
| 27H        | 40H         | L2_WRITE.LOCK.E_STATE | Counts number of L2 demand lock RFO requests where the cache line to be loaded is in the E (exclusive) state.                  |         |
| 27H        | 80H         | L2_WRITE.LOCK.M_STATE | Counts number of L2 demand lock RFO requests where the cache line to be loaded is in the M (modified) state.                   |         |
| 27H        | E0H         | L2_WRITE.LOCK.HIT     | Counts number of L2 demand lock RFO requests where the cache line to be loaded is in either the S, E, or M state.              |         |
| 27H        | F0H         | L2_WRITE.LOCK.MESI    | Counts all L2 demand lock RFO requests.                                                                                        |         |
| 28H        | 01H         | L1D_WB_L2.I_STATE     | Counts number of L1 writebacks to the L2 where the cache line to be written is in the I (invalid) state, i.e. a cache miss.    |         |
| 28H        | 02H         | L1D_WB_L2.S_STATE     | Counts number of L1 writebacks to the L2 where the cache line to be written is in the S state.                                 |         |
| 28H        | 04H         | L1D_WB_L2.E_STATE     | Counts number of L1 writebacks to the L2 where the cache line to be written is in the E (exclusive) state.                     |         |
| 28H        | 08H         | L1D_WB_L2.M_STATE     | Counts number of L1 writebacks to the L2 where the cache line to be written is in the M (modified) state.                      |         |
| 28H        | 0FH         | L1D_WB_L2.MESI        | Counts all L1 writebacks to the L2 .                                                                                           |         |

**Table A-6. Non-Architectural Performance Events In the Processor Core for Processors Based on Intel Microarchitecture Code Name Westmere**

| Event Num. | Umask Value | Event Mask Mnemonic        | Description                                                                                                                                                                                                                              | Comment       |
|------------|-------------|----------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------|
| 2EH        | 02H         | L3_LAT_CACHE.REFERENCE     | Counts uncore Last Level Cache references. Because cache hierarchy, cache sizes and other implementation-specific characteristics; value comparison to estimate performance differences is not recommended.                              | see Table A-1 |
| 2EH        | 01H         | L3_LAT_CACHE.MISS          | Counts uncore Last Level Cache misses. Because cache hierarchy, cache sizes and other implementation-specific characteristics; value comparison to estimate performance differences is not recommended.                                  | see Table A-1 |
| 3CH        | 00H         | CPU_CLK_UNHALTED.THREAD_P  | Counts the number of thread cycles while the thread is not in a halt state. The thread enters the halt state when it is running the HLT instruction. The core frequency may change from time to time due to power or thermal throttling. | see Table A-1 |
| 3CH        | 01H         | CPU_CLK_UNHALTED.REF_P     | Increments at the frequency of TSC when not halted.                                                                                                                                                                                      | see Table A-1 |
| 49H        | 01H         | DTLB_MISSES.ANY            | Counts the number of misses in the STLB which causes a page walk.                                                                                                                                                                        |               |
| 49H        | 02H         | DTLB_MISSES.WALK_COMPLETED | Counts number of misses in the STLB which resulted in a completed page walk.                                                                                                                                                             |               |
| 49H        | 04H         | DTLB_MISSES.WALK_CYCLES    | Counts cycles of page walk due to misses in the STLB.                                                                                                                                                                                    |               |
| 49H        | 10H         | DTLB_MISSES.STLB_HIT       | Counts the number of DTLB first level misses that hit in the second level TLB. This event is only relevant if the core contains multiple DTLB levels.                                                                                    |               |
| 49H        | 20H         | DTLB_MISSES.PDE_MISS       | Number of DTLB misses caused by low part of address, includes references to 2M pages because 2M pages do not use the PDE.                                                                                                                |               |

## PERFORMANCE-MONITORING EVENTS

**Table A-6. Non-Architectural Performance Events In the Processor Core for Processors Based on Intel Microarchitecture Code Name Westmere**

| Event Num. | Umask Value | Event Mask Mnemonic              | Description                                                                                                                                                                                                                                                                                                                                           | Comment           |
|------------|-------------|----------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------|
| 49H        | 80H         | DTLB_MISSES.LARGE_WALK_COMPLETED | Counts number of completed large page walks due to misses in the STLB.                                                                                                                                                                                                                                                                                |                   |
| 4CH        | 01H         | LOAD_HIT_PRE                     | Counts load operations sent to the L1 data cache while a previous SSE prefetch instruction to the same cache line has started prefetching but has not yet finished.                                                                                                                                                                                   | Counter 0, 1 only |
| 4EH        | 01H         | L1D_PREFETCH.REQUESTS            | Counts number of hardware prefetch requests dispatched out of the prefetch FIFO.                                                                                                                                                                                                                                                                      | Counter 0, 1 only |
| 4EH        | 02H         | L1D_PREFETCH.MISS                | Counts number of hardware prefetch requests that miss the L1D. There are two prefetchers in the L1D. A streamer, which predicts lines sequentially after this one should be fetched, and the IP prefetcher that remembers access patterns for the current instruction. The streamer prefetcher stops on an L1D hit, while the IP prefetcher does not. | Counter 0, 1 only |
| 4EH        | 04H         | L1D_PREFETCH.TRIGGERS            | Counts number of prefetch requests triggered by the Finite State Machine and pushed into the prefetch FIFO. Some of the prefetch requests are dropped due to overwrites or competition between the IP index prefetcher and streamer prefetcher. The prefetch FIFO contains 4 entries.                                                                 | Counter 0, 1 only |
| 4FH        | 10H         | EPT.WALK_CYCLES                  | Counts Extended Page walk cycles.                                                                                                                                                                                                                                                                                                                     |                   |
| 51H        | 01H         | L1D.REPL                         | Counts the number of lines brought into the L1 data cache.                                                                                                                                                                                                                                                                                            | Counter 0, 1 only |
| 51H        | 02H         | L1D.M_REPL                       | Counts the number of modified lines brought into the L1 data cache.                                                                                                                                                                                                                                                                                   | Counter 0, 1 only |
| 51H        | 04H         | L1D.M_EVICT                      | Counts the number of modified lines evicted from the L1 data cache due to replacement.                                                                                                                                                                                                                                                                | Counter 0, 1 only |

**Table A-6. Non-Architectural Performance Events In the Processor Core for Processors Based on Intel Microarchitecture Code Name Westmere**

| Event Num. | Umask Value | Event Mask Mnemonic                           | Description                                                                                                                                                                                                                                                                                    | Comment                                                                                                                       |
|------------|-------------|-----------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------|
| 51H        | 08H         | L1D.M_SNOOP_EVICT                             | Counts the number of modified lines evicted from the L1 data cache due to snoop HITM intervention.                                                                                                                                                                                             | Counter 0, 1 only                                                                                                             |
| 52H        | 01H         | L1D_CACHE_PREFETCH_LOCK_FB_HIT                | Counts the number of cacheable load lock speculated instructions accepted into the fill buffer.                                                                                                                                                                                                |                                                                                                                               |
| 60H        | 01H         | OFFCORE_REQUESTS_OUTSTANDING.DEMAND.READ_DATA | Counts weighted cycles of offcore demand data read requests. Does not include L2 prefetch requests.                                                                                                                                                                                            | counter 0                                                                                                                     |
| 60H        | 02H         | OFFCORE_REQUESTS_OUTSTANDING.DEMAND.READ_CODE | Counts weighted cycles of offcore demand code read requests. Does not include L2 prefetch requests.                                                                                                                                                                                            | counter 0                                                                                                                     |
| 60H        | 04H         | OFFCORE_REQUESTS_OUTSTANDING.DEMAND.RFO       | Counts weighted cycles of offcore demand RFO requests. Does not include L2 prefetch requests.                                                                                                                                                                                                  | counter 0                                                                                                                     |
| 60H        | 08H         | OFFCORE_REQUESTS_OUTSTANDING.ANY.READ         | Counts weighted cycles of offcore read requests of any kind. Include L2 prefetch requests.                                                                                                                                                                                                     | counter 0                                                                                                                     |
| 63H        | 01H         | CACHE_LOCK_CYCLE.S.L1D_L2                     | Cycle count during which the L1D and L2 are locked. A lock is asserted when there is a locked memory access, due to uncacheable memory, a locked operation that spans two cache lines, or a page walk from an uncacheable page table. This event does not cause locks, it merely detects them. | Counter 0, 1 only. L1D and L2 locks have a very high performance penalty and it is highly recommended to avoid such accesses. |
| 63H        | 02H         | CACHE_LOCK_CYCLE.S.L1D                        | Counts the number of cycles that cacheline in the L1 data cache unit is locked.                                                                                                                                                                                                                | Counter 0, 1 only.                                                                                                            |
| 6CH        | 01H         | IO_TRANSACTIONS                               | Counts the number of completed I/O transactions.                                                                                                                                                                                                                                               |                                                                                                                               |
| 80H        | 01H         | L1I.HITS                                      | Counts all instruction fetches that hit the L1 instruction cache.                                                                                                                                                                                                                              |                                                                                                                               |

## PERFORMANCE-MONITORING EVENTS

**Table A-6. Non-Architectural Performance Events In the Processor Core for Processors Based on Intel Microarchitecture Code Name Westmere**

| Event Num. | Umask Value | Event Mask Mnemonic              | Description                                                                                                                                                                                                                                                          | Comment |
|------------|-------------|----------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------|
| 80H        | 02H         | L1I.MISSES                       | Counts all instruction fetches that miss the L1I cache. This includes instruction cache misses, streaming buffer misses, victim cache misses and uncacheable fetches. An instruction fetch miss is counted only once and not once for every cycle it is outstanding. |         |
| 80H        | 03H         | L1I.READS                        | Counts all instruction fetches, including uncacheable fetches that bypass the L1I.                                                                                                                                                                                   |         |
| 80H        | 04H         | L1I.CYCLES_STALLED               | Cycle counts for which an instruction fetch stalls due to a L1I cache miss, ITLB miss or ITLB fault.                                                                                                                                                                 |         |
| 82H        | 01H         | LARGE_ITLB.HIT                   | Counts number of large ITLB hits.                                                                                                                                                                                                                                    |         |
| 85H        | 01H         | ITLB_MISSES.ANY                  | Counts the number of misses in all levels of the ITLB which causes a page walk.                                                                                                                                                                                      |         |
| 85H        | 02H         | ITLB_MISSES.WALK_COMPLETED       | Counts number of misses in all levels of the ITLB which resulted in a completed page walk.                                                                                                                                                                           |         |
| 85H        | 04H         | ITLB_MISSES.WALK_CYCLES          | Counts ITLB miss page walk cycles.                                                                                                                                                                                                                                   |         |
| 85H        | 80H         | ITLB_MISSES.LARGE_WALK_COMPLETED | Counts number of completed large page walks due to misses in the STLB.                                                                                                                                                                                               |         |
| 87H        | 01H         | ILD_STALL.LCP                    | Cycles Instruction Length Decoder stalls due to length changing prefixes: 66, 67 or REX.W (for EM64T) instructions which change the length of the decoded instruction.                                                                                               |         |
| 87H        | 02H         | ILD_STALL.MRU                    | Instruction Length Decoder stall cycles due to Brand Prediction Unit (PBU) Most Recently Used (MRU) bypass.                                                                                                                                                          |         |
| 87H        | 04H         | ILD_STALL.IQ_FULL                | Stall cycles due to a full instruction queue.                                                                                                                                                                                                                        |         |

**Table A-6. Non-Architectural Performance Events In the Processor Core for Processors Based on Intel Microarchitecture Code Name Westmere**

| Event Num. | Umask Value | Event Mask Mnemonic             | Description                                                                                                                                                                                                                                       | Comment |
|------------|-------------|---------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------|
| 87H        | 08H         | ILD_STALL.REGEN                 | Counts the number of regen stalls.                                                                                                                                                                                                                |         |
| 87H        | 0FH         | ILD_STALL.ANY                   | Counts any cycles the Instruction Length Decoder is stalled.                                                                                                                                                                                      |         |
| 88H        | 01H         | BR_INST_EXEC.COND               | Counts the number of conditional near branch instructions executed, but not necessarily retired.                                                                                                                                                  |         |
| 88H        | 02H         | BR_INST_EXEC.DIRECT             | Counts all unconditional near branch instructions excluding calls and indirect branches.                                                                                                                                                          |         |
| 88H        | 04H         | BR_INST_EXEC.INDIRECT_NON_CALL  | Counts the number of executed indirect near branch instructions that are not calls.                                                                                                                                                               |         |
| 88H        | 07H         | BR_INST_EXEC.NON_CALLS          | Counts all non call near branch instructions executed, but not necessarily retired.                                                                                                                                                               |         |
| 88H        | 08H         | BR_INST_EXEC.RETURN_NEAR        | Counts indirect near branches that have a return mnemonic.                                                                                                                                                                                        |         |
| 88H        | 10H         | BR_INST_EXEC.DIRECT_NEAR_CALL   | Counts unconditional near call branch instructions, excluding non call branch, executed.                                                                                                                                                          |         |
| 88H        | 20H         | BR_INST_EXEC.INDIRECT_NEAR_CALL | Counts indirect near calls, including both register and memory indirect, executed.                                                                                                                                                                |         |
| 88H        | 30H         | BR_INST_EXEC.NEAR_CALLS         | Counts all near call branches executed, but not necessarily retired.                                                                                                                                                                              |         |
| 88H        | 40H         | BR_INST_EXEC.TAKEN              | Counts taken near branches executed, but not necessarily retired.                                                                                                                                                                                 |         |
| 88H        | 7FH         | BR_INST_EXEC.ANY                | Counts all near executed branches (not necessarily retired). This includes only instructions and not micro-op branches. Frequent branching is not necessarily a major performance issue. However frequent branch mispredictions may be a problem. |         |

## PERFORMANCE-MONITORING EVENTS

**Table A-6. Non-Architectural Performance Events In the Processor Core for Processors Based on Intel Microarchitecture Code Name Westmere**

| Event Num. | Umask Value | Event Mask Mnemonic             | Description                                                                                                                   | Comment |
|------------|-------------|---------------------------------|-------------------------------------------------------------------------------------------------------------------------------|---------|
| 89H        | 01H         | BR_MISP_EXEC.COND               | Counts the number of mispredicted conditional near branch instructions executed, but not necessarily retired.                 |         |
| 89H        | 02H         | BR_MISP_EXEC.DIRECT             | Counts mispredicted macro unconditional near branch instructions, excluding calls and indirect branches (should always be 0). |         |
| 89H        | 04H         | BR_MISP_EXEC.INDIRECT_NON_CALL  | Counts the number of executed mispredicted indirect near branch instructions that are not calls.                              |         |
| 89H        | 07H         | BR_MISP_EXEC.NON_CALLS          | Counts mispredicted non call near branches executed, but not necessarily retired.                                             |         |
| 89H        | 08H         | BR_MISP_EXEC.RETURN_NEAR        | Counts mispredicted indirect branches that have a rear return mnemonic.                                                       |         |
| 89H        | 10H         | BR_MISP_EXEC.DIRECT_NEAR_CALL   | Counts mispredicted non-indirect near calls executed, (should always be 0).                                                   |         |
| 89H        | 20H         | BR_MISP_EXEC.INDIRECT_NEAR_CALL | Counts mispredicted indirect near calls executed, including both register and memory indirect.                                |         |
| 89H        | 30H         | BR_MISP_EXEC.NEAR_CALLS         | Counts all mispredicted near call branches executed, but not necessarily retired.                                             |         |
| 89H        | 40H         | BR_MISP_EXEC.TAKEN              | Counts executed mispredicted near branches that are taken, but not necessarily retired.                                       |         |
| 89H        | 7FH         | BR_MISP_EXEC.ANY                | Counts the number of mispredicted near branch instructions that were executed, but not necessarily retired.                   |         |

**Table A-6. Non-Architectural Performance Events In the Processor Core for Processors Based on Intel Microarchitecture Code Name Westmere**

| Event Num. | Umask Value | Event Mask Mnemonic      | Description                                                                                                                                                                                                                                                                                                                                                                                                       | Comment                                                                                      |
|------------|-------------|--------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------|
| A2H        | 01H         | RESOURCE_STALLS.ANY      | Counts the number of Allocator resource related stalls. Includes register renaming buffer entries, memory buffer entries. In addition to resource related stalls, this event counts some other events. Includes stalls arising during branch misprediction recovery, such as if retirement of the mispredicted branch is delayed and stalls arising while store buffer is draining from synchronizing operations. | Does not include stalls due to SuperQ (off core) queue full, too many cache misses, etc.     |
| A2H        | 02H         | RESOURCE_STALLS.LOAD     | Counts the cycles of stall due to lack of load buffer for load operation.                                                                                                                                                                                                                                                                                                                                         |                                                                                              |
| A2H        | 04H         | RESOURCE_STALLS.RS_FULL  | This event counts the number of cycles when the number of instructions in the pipeline waiting for execution reaches the limit the processor can handle. A high count of this event indicates that there are long latency operations in the pipe (possibly load and store operations that miss the L2 cache, or instructions dependent upon instructions further down the pipeline that have yet to retire).      | When RS is full, new instructions can not enter the reservation station and start execution. |
| A2H        | 08H         | RESOURCE_STALLS.STORE    | This event counts the number of cycles that a resource related stall will occur due to the number of store instructions reaching the limit of the pipeline, (i.e. all store buffers are used). The stall ends when a store instruction commits its data to the cache or memory.                                                                                                                                   |                                                                                              |
| A2H        | 10H         | RESOURCE_STALLS.ROB_FULL | Counts the cycles of stall due to re-order buffer full.                                                                                                                                                                                                                                                                                                                                                           |                                                                                              |
| A2H        | 20H         | RESOURCE_STALLS.FPCW     | Counts the number of cycles while execution was stalled due to writing the floating-point unit (FPU) control word.                                                                                                                                                                                                                                                                                                |                                                                                              |

## PERFORMANCE-MONITORING EVENTS

**Table A-6. Non-Architectural Performance Events In the Processor Core for Processors Based on Intel Microarchitecture Code Name Westmere**

| Event Num. | Umask Value | Event Mask Mnemonic                   | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        | Comment                                |
|------------|-------------|---------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------|
| A2H        | 40H         | RESOURCE_STALLS.<br>MXCSR             | Stalls due to the MXCSR register rename occurring to close to a previous MXCSR rename. The MXCSR provides control and status for the MMX registers.                                                                                                                                                                                                                                                                                                                                                                                                |                                        |
| A2H        | 80H         | RESOURCE_STALLS.<br>OTHER             | Counts the number of cycles while execution was stalled due to other resource issues.                                                                                                                                                                                                                                                                                                                                                                                                                                                              |                                        |
| A6H        | 01H         | MACRO_INSTS.FUSION<br>NS_DECODED      | Counts the number of instructions decoded that are macro-fused but not necessarily executed or retired.                                                                                                                                                                                                                                                                                                                                                                                                                                            |                                        |
| A7H        | 01H         | BACLEAR_FORCE_IQ                      | Counts number of times a BACLEAR was forced by the Instruction Queue. The IQ is also responsible for providing conditional branch prediction direction based on a static scheme and dynamic data provided by the L2 Branch Prediction Unit. If the conditional branch target is not found in the Target Array and the IQ predicts that the branch is taken, then the IQ will force the Branch Address Calculator to issue a BACLEAR. Each BACLEAR asserted by the BAC generates approximately an 8 cycle bubble in the instruction fetch pipeline. |                                        |
| A8H        | 01H         | LSD.UOPS                              | Counts the number of micro-ops delivered by loop stream detector.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  | Use cmask=1 and invert to count cycles |
| AEH        | 01H         | ITLB_FLUSH                            | Counts the number of ITLB flushes.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |                                        |
| BOH        | 01H         | OFFCORE_REQUEST<br>S.DEMAND.READ_DATA | Counts number of offcore demand data read requests. Does not count L2 prefetch requests.                                                                                                                                                                                                                                                                                                                                                                                                                                                           |                                        |
| BOH        | 02H         | OFFCORE_REQUEST<br>S.DEMAND.READ_CODE | Counts number of offcore demand code read requests. Does not count L2 prefetch requests.                                                                                                                                                                                                                                                                                                                                                                                                                                                           |                                        |

**Table A-6. Non-Architectural Performance Events In the Processor Core for Processors Based on Intel Microarchitecture Code Name Westmere**

| Event Num. | Umask Value | Event Mask Mnemonic             | Description                                                                                                                                                                                          | Comment |
|------------|-------------|---------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------|
| BOH        | 04H         | OFFCORE_REQUEST S.DEMAND.RFO    | Counts number of offcore demand RFO requests. Does not count L2 prefetch requests.                                                                                                                   |         |
| BOH        | 08H         | OFFCORE_REQUEST S.ANY.READ      | Counts number of offcore read requests. Includes L2 prefetch requests.                                                                                                                               |         |
| BOH        | 10H         | OFFCORE_REQUEST S.ANY.RFO       | Counts number of offcore RFO requests. Includes L2 prefetch requests.                                                                                                                                |         |
| BOH        | 40H         | OFFCORE_REQUEST S.L1D_WRITEBACK | Counts number of L1D writebacks to the uncore.                                                                                                                                                       |         |
| BOH        | 80H         | OFFCORE_REQUEST S.ANY           | Counts all offcore requests.                                                                                                                                                                         |         |
| B1H        | 01H         | UOPS_EXECUTED.PO RT0            | Counts number of Uops executed that were issued on port 0. Port 0 handles integer arithmetic, SIMD and FP add Uops.                                                                                  |         |
| B1H        | 02H         | UOPS_EXECUTED.PO RT1            | Counts number of Uops executed that were issued on port 1. Port 1 handles integer arithmetic, SIMD, integer shift, FP multiply and FP divide Uops.                                                   |         |
| B1H        | 04H         | UOPS_EXECUTED.PO RT2_CORE       | Counts number of Uops executed that were issued on port 2. Port 2 handles the load Uops. This is a core count only and can not be collected per thread.                                              |         |
| B1H        | 08H         | UOPS_EXECUTED.PO RT3_CORE       | Counts number of Uops executed that were issued on port 3. Port 3 handles store Uops. This is a core count only and can not be collected per thread.                                                 |         |
| B1H        | 10H         | UOPS_EXECUTED.PO RT4_CORE       | Counts number of Uops executed that were issued on port 4. Port 4 handles the value to be stored for the store Uops issued on port 3. This is a core count only and can not be collected per thread. |         |

## PERFORMANCE-MONITORING EVENTS

**Table A-6. Non-Architectural Performance Events In the Processor Core for Processors Based on Intel Microarchitecture Code Name Westmere**

| Event Num. | Umask Value | Event Mask Mnemonic                         | Description                                                                                                                                                    | Comment                                     |
|------------|-------------|---------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------|
| B1H        | 1FH         | UOPS_EXECUTED.CO RE_ACTIVE_CYCLES_ NO_PORT5 | Counts number of cycles there are one or more uops being executed and were issued on ports 0-4. This is a core count only and can not be collected per thread. |                                             |
| B1H        | 20H         | UOPS_EXECUTED.PO RT5                        | Counts number of Uops executed that where issued on port 5.                                                                                                    |                                             |
| B1H        | 3FH         | UOPS_EXECUTED.CO RE_ACTIVE_CYCLES           | Counts number of cycles there are one or more uops being executed on any ports. This is a core count only and can not be collected per thread.                 |                                             |
| B1H        | 40H         | UOPS_EXECUTED.PO RT015                      | Counts number of Uops executed that where issued on port 0, 1, or 5.                                                                                           | use cmask=1, invert=1 to count stall cycles |
| B1H        | 80H         | UOPS_EXECUTED.PO RT234                      | Counts number of Uops executed that where issued on port 2, 3, or 4.                                                                                           |                                             |
| B2H        | 01H         | OFFCORE_REQUEST_S_SQ_FULL                   | Counts number of cycles the SQ is full to handle off-core requests.                                                                                            |                                             |
| B3H        | 01H         | SNOOPQ_REQUESTS _OUTSTANDING.DAT A          | Counts weighted cycles of snoopq requests for data. Counter 0 only.                                                                                            | Use cmask=1 to count cycles not empty.      |
| B3H        | 02H         | SNOOPQ_REQUESTS _OUTSTANDING.INVA LIDATE    | Counts weighted cycles of snoopq invalidate requests. Counter 0 only.                                                                                          | Use cmask=1 to count cycles not empty.      |
| B3H        | 04H         | SNOOPQ_REQUESTS _OUTSTANDING.COD E          | Counts weighted cycles of snoopq requests for code. Counter 0 only.                                                                                            | Use cmask=1 to count cycles not empty.      |
| B4H        | 01H         | SNOOPQ_REQUESTS. CODE                       | Counts the number of snoop code requests.                                                                                                                      |                                             |
| B4H        | 02H         | SNOOPQ_REQUESTS. DATA                       | Counts the number of snoop data requests.                                                                                                                      |                                             |
| B4H        | 04H         | SNOOPQ_REQUESTS. INVALIDATE                 | Counts the number of snoop invalidate requests.                                                                                                                |                                             |
| B7H        | 01H         | OFF_CORE_RESPON S_E_0                       | see Section 30.6.1.3, "Off-core Response Performance Monitoring in the Processor Core"                                                                         | Requires programming MSR 01A6H              |

**Table A-6. Non-Architectural Performance Events In the Processor Core for Processors Based on Intel Microarchitecture Code Name Westmere**

| Event Num. | Umask Value | Event Mask Mnemonic | Description                                                                                                                                                                                                                                                                                                       | Comment                                                                                                                        |
|------------|-------------|---------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------|
| B8H        | 01H         | SNOOP_RESPONSE.HIT  | Counts HIT snoop response sent by this thread in response to a snoop request.                                                                                                                                                                                                                                     |                                                                                                                                |
| B8H        | 02H         | SNOOP_RESPONSE.HITE | Counts HIT E snoop response sent by this thread in response to a snoop request.                                                                                                                                                                                                                                   |                                                                                                                                |
| B8H        | 04H         | SNOOP_RESPONSE.HITM | Counts HIT M snoop response sent by this thread in response to a snoop request.                                                                                                                                                                                                                                   |                                                                                                                                |
| BBH        | 01H         | OFF_CORE_RESPONSE_1 | see Section 30.6.1.3, "Off-core Response Performance Monitoring in the Processor Core"                                                                                                                                                                                                                            | Use MSR 01A7H                                                                                                                  |
| COH        | 01H         | INST_RETIREDA.NY_P  | See Table A-1<br>Notes: INST_RETIREDA.NY is counted by a designated fixed counter. INST_RETIREDA.NY_P is counted by a programmable counter and is an architectural performance event. Event is supported if CPUID.A.EBX[1] = 0.                                                                                   | Counting:<br>Faulting<br>executions of<br>GETSEC/VM<br>entry/VM<br>Exit/MWait will<br>not count as<br>retired<br>instructions. |
| COH        | 02H         | INST_RETIREDA.X87   | Counts the number of floating point computational operations retired: floating point computational operations executed by the assist handler and sub-operations of complex floating point instructions like transcendental instructions.                                                                          |                                                                                                                                |
| COH        | 04H         | INST_RETIREDA.MMX   | Counts the number of retired: MMX instructions.                                                                                                                                                                                                                                                                   |                                                                                                                                |
| C2H        | 01H         | UOPS_RETIREDA.NY    | Counts the number of micro-ops retired, (macro-fused=1, micro-fused=2, others=1; maximum count of 8 per cycle). Most instructions are composed of one or two micro-ops. Some instructions are decoded into longer sequences such as repeat instructions, floating point transcendental instructions, and assists. | Use cmask=1 and invert to count active cycles or stalled cycles                                                                |

## PERFORMANCE-MONITORING EVENTS

**Table A-6. Non-Architectural Performance Events In the Processor Core for Processors Based on Intel Microarchitecture Code Name Westmere**

| Event Num. | Umask Value | Event Mask Mnemonic            | Description                                                                                                                                                                                                            | Comment       |
|------------|-------------|--------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------|
| C2H        | 02H         | UOPS_RETIRED.RETIRED_SLOTS     | Counts the number of retirement slots used each cycle                                                                                                                                                                  |               |
| C2H        | 04H         | UOPS_RETIRED.MACRO_FUSED       | Counts number of macro-fused uops retired.                                                                                                                                                                             |               |
| C3H        | 01H         | MACHINE_CLEARSCYCLES           | Counts the cycles machine clear is asserted.                                                                                                                                                                           |               |
| C3H        | 02H         | MACHINE_CLEARSMEM_ORDER        | Counts the number of machine clears due to memory order conflicts.                                                                                                                                                     |               |
| C3H        | 04H         | MACHINE_CLEARSSMC              | Counts the number of times that a program writes to a code section. Self-modifying code causes a severe penalty in all Intel 64 and IA-32 processors. The modified cache line is written back to the L2 and L3 caches. |               |
| C4H        | 00H         | BR_INST_RETIREDA_LL_BRANCHES   | Branch instructions at retirement                                                                                                                                                                                      | See Table A-1 |
| C4H        | 01H         | BR_INST_RETIREDCCONDITIONAL    | Counts the number of conditional branch instructions retired.                                                                                                                                                          |               |
| C4H        | 02H         | BR_INST_RETIREDNNEAR_CALL      | Counts the number of direct & indirect near unconditional calls retired.                                                                                                                                               |               |
| C4H        | 04H         | BR_INST_RETIREDA_LL_BRANCHES   | Counts the number of branch instructions retired.                                                                                                                                                                      |               |
| C5H        | 00H         | BR_MISP_RETIREDA_LL_BRANCHES   | Mispredicted branch instructions at retirement                                                                                                                                                                         | See Table A-1 |
| C5H        | 01H         | BR_MISP_RETIREDCCONDITIONAL    | Counts mispredicted conditional retired calls.                                                                                                                                                                         |               |
| C5H        | 02H         | BR_MISP_RETIREDNNEAR_CALL      | Counts mispredicted direct & indirect near unconditional retired calls.                                                                                                                                                |               |
| C5H        | 04H         | BR_MISP_RETIREDA_LL_BRANCHES   | Counts all mispredicted retired calls.                                                                                                                                                                                 |               |
| C7H        | 01H         | SSEX_UOPS_RETIREDPACKED_SINGLE | Counts SIMD packed single-precision floating point Uops retired.                                                                                                                                                       |               |

**Table A-6. Non-Architectural Performance Events In the Processor Core for Processors Based on Intel Microarchitecture Code Name Westmere**

| Event Num. | Umask Value | Event Mask Mnemonic                     | Description                                                                                                                                                                                      | Comment |
|------------|-------------|-----------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------|
| C7H        | 02H         | SSEX_UOPS_RETIRE<br>D.SCALAR_SINGLE     | Counts SIMD scalar single-precision floating point Uops retired.                                                                                                                                 |         |
| C7H        | 04H         | SSEX_UOPS_RETIRE<br>D.PACKED_DOUBLE     | Counts SIMD packed double-precision floating point Uops retired.                                                                                                                                 |         |
| C7H        | 08H         | SSEX_UOPS_RETIRE<br>D.SCALAR_DOUBLE     | Counts SIMD scalar double-precision floating point Uops retired.                                                                                                                                 |         |
| C7H        | 10H         | SSEX_UOPS_RETIRE<br>D.VECTOR_INTEGER    | Counts 128-bit SIMD vector integer Uops retired.                                                                                                                                                 |         |
| C8H        | 20H         | ITLB_MISS_RETIRIED                      | Counts the number of retired instructions that missed the ITLB when the instruction was fetched.                                                                                                 |         |
| CBH        | 01H         | MEM_LOAD_RETIRIED<br>.L1D_HIT           | Counts number of retired loads that hit the L1 data cache.                                                                                                                                       |         |
| CBH        | 02H         | MEM_LOAD_RETIRIED<br>.L2_HIT            | Counts number of retired loads that hit the L2 data cache.                                                                                                                                       |         |
| CBH        | 04H         | MEM_LOAD_RETIRIED<br>.L3_UNSHARED_HIT   | Counts number of retired loads that hit their own, unshared lines in the L3 cache.                                                                                                               |         |
| CBH        | 08H         | MEM_LOAD_RETIRIED<br>.OTHER_CORE_L2_HIT | Counts number of retired loads that hit in a sibling core's L2 (on die core). Since the L3 is inclusive of all cores on the package, this is an L3 hit. This counts both clean or modified hits. |         |
| CBH        | 10H         | MEM_LOAD_RETIRIED<br>.L3_MISS           | Counts number of retired loads that miss the L3 cache. The load was satisfied by a remote socket, local memory or an IOH.                                                                        |         |
| CBH        | 40H         | MEM_LOAD_RETIRIED<br>.HIT_LFB           | Counts number of retired loads that miss the L1D and the address is located in an allocated line fill buffer and will soon be committed to cache. This is counting secondary L1D misses.         |         |

## PERFORMANCE-MONITORING EVENTS

**Table A-6. Non-Architectural Performance Events In the Processor Core for Processors Based on Intel Microarchitecture Code Name Westmere**

| Event Num. | Umask Value | Event Mask Mnemonic        | Description                                                                                                                                                                                                                                                                                 | Comment |
|------------|-------------|----------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------|
| CBH        | 80H         | MEM_LOAD_RETIRED.DTLB_MISS | Counts the number of retired loads that missed the DTLB. The DTLB miss is not counted if the load operation causes a fault. This event counts loads from cacheable memory only. The event does not count loads by software prefetches. Counts both primary and secondary misses to the TLB. |         |
| CCH        | 01H         | FP_MMX_TRANS.TO_FPP        | Counts the first floating-point instruction following any MMX instruction. You can use this event to estimate the penalties for the transitions between floating-point and MMX technology states.                                                                                           |         |
| CCH        | 02H         | FP_MMX_TRANS.TOMMX         | Counts the first MMX instruction following a floating-point instruction. You can use this event to estimate the penalties for the transitions between floating-point and MMX technology states.                                                                                             |         |
| CCH        | 03H         | FP_MMX_TRANS.ANY           | Counts all transitions from floating point to MMX instructions and from MMX instructions to floating point instructions. You can use this event to estimate the penalties for the transitions between floating-point and MMX technology states.                                             |         |
| D0H        | 01H         | MACRO_INSTS.DECODED        | Counts the number of instructions decoded, (but not necessarily executed or retired).                                                                                                                                                                                                       |         |
| D1H        | 01H         | UOPS_DECODEDSTALL_CYCLES   | Counts the cycles of decoder stalls. INV=1, Cmask= 1                                                                                                                                                                                                                                        |         |
| D1H        | 02H         | UOPS_DECODED.MS            | Counts the number of Uops decoded by the Microcode Sequencer, MS. The MS delivers uops when the instruction is more than 4 uops long or a microcode assist is occurring.                                                                                                                    |         |

**Table A-6. Non-Architectural Performance Events In the Processor Core for Processors Based on Intel Microarchitecture Code Name Westmere**

| Event Num. | Umask Value | Event Mask Mnemonic      | Description                                                                                                                                                                                                                                                                                                                                                                                         | Comment |
|------------|-------------|--------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------|
| D1H        | 04H         | UOPS_DECODED.ESP_FOLDING | Counts number of stack pointer (ESP) instructions decoded: push, pop, call, ret, etc. ESP instructions do not generate a Uop to increment or decrement ESP. Instead, they update an ESP_Offset register that keeps track of the delta to the current value of the ESP register.                                                                                                                     |         |
| D1H        | 08H         | UOPS_DECODED.ESP_SYNC    | Counts number of stack pointer (ESP) sync operations where an ESP instruction is corrected by adding the ESP offset register to the current value of the ESP register.                                                                                                                                                                                                                              |         |
| D2H        | 01H         | RAT_STALLS.FLAGS         | Counts the number of cycles during which execution stalled due to several reasons, one of which is a partial flag register stall. A partial register stall may occur when two conditions are met: 1) an instruction modifies some, but not all, of the flags in the flag register and 2) the next instruction, which depends on flags, depends on flags that were not modified by this instruction. |         |
| D2H        | 02H         | RAT_STALLS.REGISTER      | This event counts the number of cycles instruction execution latency became longer than the defined latency because the instruction used a register that was partially written by previous instruction.                                                                                                                                                                                             |         |

## PERFORMANCE-MONITORING EVENTS

**Table A-6. Non-Architectural Performance Events In the Processor Core for Processors Based on Intel Microarchitecture Code Name Westmere**

| Event Num. | Umask Value | Event Mask Mnemonic      | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                   | Comment |
|------------|-------------|--------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------|
| D2H        | 04H         | RAT_STALLS.ROB_READ_PORT | Counts the number of cycles when ROB read port stalls occurred, which did not allow new micro-ops to enter the out-of-order pipeline. Note that, at this stage in the pipeline, additional stalls may occur at the same cycle and prevent the stalled micro-ops from entering the pipe. In such a case, micro-ops retry entering the execution pipe in the next cycle and the ROB-read port stall is counted again.                                                           |         |
| D2H        | 08H         | RAT_STALLS.SCOREBOARD    | Counts the cycles where we stall due to microarchitecturally required serialization. Microcode scoreboarding stalls.                                                                                                                                                                                                                                                                                                                                                          |         |
| D2H        | 0FH         | RAT_STALLS.ANY           | Counts all Register Allocation Table stall cycles due to: Cycles when ROB read port stalls occurred, which did not allow new micro-ops to enter the execution pipe. Cycles when partial register stalls occurred Cycles when flag stalls occurred Cycles floating-point unit (FPU) status word stalls occurred. To count each of these conditions separately use the events:<br>RAT_STALLS.ROB_READ_PORT,<br>RAT_STALLS.PARTIAL,<br>RAT_STALLS.FLAGS, and<br>RAT_STALLS.FPSW. |         |
| D4H        | 01H         | SEG_RENAME_STALLS        | Counts the number of stall cycles due to the lack of renaming resources for the ES, DS, FS, and GS segment registers. If a segment is renamed but not retired and a second update to the same segment occurs, a stall occurs in the front-end of the pipeline until the renamed segment retires.                                                                                                                                                                              |         |

**Table A-6. Non-Architectural Performance Events In the Processor Core for Processors Based on Intel Microarchitecture Code Name Westmere**

| Event Num. | Umask Value | Event Mask Mnemonic | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                             | Comment                                                 |
|------------|-------------|---------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------|
| D5H        | 01H         | ES_REG_RENAMES      | Counts the number of times the ES segment register is renamed.                                                                                                                                                                                                                                                                                                                                                                                                                          |                                                         |
| DBH        | 01H         | UOP_UNFUSION        | Counts unfusion events due to floating point exception to a fused uop.                                                                                                                                                                                                                                                                                                                                                                                                                  |                                                         |
| EOH        | 01H         | BR_INST_DECODED     | Counts the number of branch instructions decoded.                                                                                                                                                                                                                                                                                                                                                                                                                                       |                                                         |
| E5H        | 01H         | BPU_MISSED_CALL_RET | Counts number of times the Branch Prediciton Unit missed predicting a call or return branch.                                                                                                                                                                                                                                                                                                                                                                                            |                                                         |
| E6H        | 01H         | BACLEAR.CLEAR       | Counts the number of times the front end is resteered, mainly when the Branch Prediction Unit cannot provide a correct prediction and this is corrected by the Branch Address Calculator at the front end. This can occur if the code has many branches such that they cannot be consumed by the BPU. Each BACLEAR asserted by the BAC generates approximately an 8 cycle bubble in the instruction fetch pipeline. The effect on total execution time depends on the surrounding code. |                                                         |
| E6H        | 02H         | BACLEAR.BAD_TARGET  | Counts number of Branch Address Calculator clears (BACLEAR) asserted due to conditional branch instructions in which there was a target hit but the direction was wrong. Each BACLEAR asserted by the BAC generates approximately an 8 cycle bubble in the instruction fetch pipeline.                                                                                                                                                                                                  |                                                         |
| E8H        | 01H         | BPU_CLEAR.EARLY     | Counts early (normal) Branch Prediction Unit clears: BPU predicted a taken branch after incorrectly assuming that it was not taken.                                                                                                                                                                                                                                                                                                                                                     | The BPU clear leads to 2 cycle bubble in the Front End. |

## PERFORMANCE-MONITORING EVENTS

**Table A-6. Non-Architectural Performance Events In the Processor Core for Processors Based on Intel Microarchitecture Code Name Westmere**

| Event Num. | Umask Value | Event Mask Mnemonic         | Description                                                                                                                              | Comment |
|------------|-------------|-----------------------------|------------------------------------------------------------------------------------------------------------------------------------------|---------|
| E8H        | 02H         | BPU_CLEAR.S.LATE            | Counts late Branch Prediction Unit clears due to Most Recently Used conflicts. The PBU clear leads to a 3 cycle bubble in the Front End. |         |
| ECH        | 01H         | THREAD_ACTIVE               | Counts cycles threads are active.                                                                                                        |         |
| FOH        | 01H         | L2_TRANSACTIONS.L.OAD       | Counts L2 load operations due to HW prefetch or demand loads.                                                                            |         |
| FOH        | 02H         | L2_TRANSACTIONS.RFO         | Counts L2 RFO operations due to HW prefetch or demand RFOs.                                                                              |         |
| FOH        | 04H         | L2_TRANSACTIONS.I.FETCH     | Counts L2 instruction fetch operations due to HW prefetch or demand ifetch.                                                              |         |
| FOH        | 08H         | L2_TRANSACTIONS.PREFETCH    | Counts L2 prefetch operations.                                                                                                           |         |
| FOH        | 10H         | L2_TRANSACTIONS.L.1D_WB     | Counts L1D writeback operations to the L2.                                                                                               |         |
| FOH        | 20H         | L2_TRANSACTIONS.FILL        | Counts L2 cache line fill operations due to load, RFO, L1D writeback or prefetch.                                                        |         |
| FOH        | 40H         | L2_TRANSACTIONS.WB          | Counts L2 writeback operations to the L3.                                                                                                |         |
| FOH        | 80H         | L2_TRANSACTIONS.ANY         | Counts all L2 cache operations.                                                                                                          |         |
| F1H        | 02H         | L2_LINES_IN.S_STATE         | Counts the number of cache lines allocated in the L2 cache in the S (shared) state.                                                      |         |
| F1H        | 04H         | L2_LINES_IN.E_STATE         | Counts the number of cache lines allocated in the L2 cache in the E (exclusive) state.                                                   |         |
| F1H        | 07H         | L2_LINES_IN.ANY             | Counts the number of cache lines allocated in the L2 cache.                                                                              |         |
| F2H        | 01H         | L2_LINES_OUT.DEMAND_CLEAN   | Counts L2 clean cache lines evicted by a demand request.                                                                                 |         |
| F2H        | 02H         | L2_LINES_OUT.DEMAND_DIRTY   | Counts L2 dirty (modified) cache lines evicted by a demand request.                                                                      |         |
| F2H        | 04H         | L2_LINES_OUT.PREFETCH_CLEAN | Counts L2 clean cache line evicted by a prefetch request.                                                                                |         |

**Table A-6. Non-Architectural Performance Events In the Processor Core for Processors Based on Intel Microarchitecture Code Name Westmere**

| Event Num. | Umask Value | Event Mask Mnemonic         | Description                                                                                                                                                                                                                                                                                                                                                                                | Comment |
|------------|-------------|-----------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------|
| F2H        | 08H         | L2_LINES_OUT.PREFETCH_DIRTY | Counts L2 modified cache line evicted by a prefetch request.                                                                                                                                                                                                                                                                                                                               |         |
| F2H        | 0FH         | L2_LINES_OUT.ANY            | Counts all L2 cache lines evicted for any reason.                                                                                                                                                                                                                                                                                                                                          |         |
| F4H        | 04H         | SQ_MISC.LRU_HINTS           | Counts number of Super Queue LRU hints sent to L3.                                                                                                                                                                                                                                                                                                                                         |         |
| F4H        | 10H         | SQ_MISC.SPLIT_LOCK          | Counts the number of SQ lock splits across a cache line.                                                                                                                                                                                                                                                                                                                                   |         |
| F6H        | 01H         | SQ_FULL_STALL_CYCLE         | Counts cycles the Super Queue is full. Neither of the threads on this core will be able to access the uncore.                                                                                                                                                                                                                                                                              |         |
| F7H        | 01H         | FP_ASSIST.ALL               | Counts the number of floating point operations executed that required micro-code assist intervention. Assists are required in the following cases: SSE instructions, (Denormal input when the DAZ flag is off or Underflow result when the FTZ flag is off); x87 instructions, (NaN or denormal are loaded to a register or used as input from memory, Division by 0 or Underflow output). |         |
| F7H        | 02H         | FP_ASSIST.OUTPUT            | Counts number of floating point micro-code assist when the output value (destination register) is invalid.                                                                                                                                                                                                                                                                                 |         |
| F7H        | 04H         | FP_ASSIST.INPUT             | Counts number of floating point micro-code assist when the input value (one of the source operands to an FP instruction) is invalid.                                                                                                                                                                                                                                                       |         |
| FDH        | 01H         | SIMD_INT_64.PACKED_MPY      | Counts number of SIMD integer 64 bit packed multiply operations.                                                                                                                                                                                                                                                                                                                           |         |
| FDH        | 02H         | SIMD_INT_64.PACKED_SHIFT    | Counts number of SIMD integer 64 bit packed shift operations.                                                                                                                                                                                                                                                                                                                              |         |
| FDH        | 04H         | SIMD_INT_64.PACK            | Counts number of SIMD integer 64 bit pack operations.                                                                                                                                                                                                                                                                                                                                      |         |
| FDH        | 08H         | SIMD_INT_64.UNPACK          | Counts number of SIMD integer 64 bit unpack operations.                                                                                                                                                                                                                                                                                                                                    |         |

## PERFORMANCE-MONITORING EVENTS

**Table A-6. Non-Architectural Performance Events In the Processor Core for Processors Based on Intel Microarchitecture Code Name Westmere**

| Event Num. | Umask Value | Event Mask Mnemonic        | Description                                                    | Comment |
|------------|-------------|----------------------------|----------------------------------------------------------------|---------|
| FDH        | 10H         | SIMD_INT_64.PACKED_LOGICAL | Counts number of SIMD integer 64 bit logical operations.       |         |
| FDH        | 20H         | SIMD_INT_64.PACKED_ARITH   | Counts number of SIMD integer 64 bit arithmetic operations.    |         |
| FDH        | 40H         | SIMD_INT_64.SHUFFLE_MOVE   | Counts number of SIMD integer 64 bit shift or move operations. |         |

Non-architectural Performance monitoring events of the uncore sub-system for Processors with CPUID signature of DisplayFamily\_DisplayModel 06\_25H, 06\_2CH, and 06\_1FH support performance events listed in Table A-7.

**Table A-7. Non-Architectural Performance Events In the Processor Uncore for Processors Based on Intel Microarchitecture Code Name Westmere**

| Event Num. | Umask Value | Event Mask Mnemonic                         | Description                                                                                                                                        | Comment |
|------------|-------------|---------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------|---------|
| 00H        | 01H         | UNC_GQ_CYCLES_FU_LL.READ_TRACKER            | Uncore cycles Global Queue read tracker is full.                                                                                                   |         |
| 00H        | 02H         | UNC_GQ_CYCLES_FU_LL.WRITE_TRACKER           | Uncore cycles Global Queue write tracker is full.                                                                                                  |         |
| 00H        | 04H         | UNC_GQ_CYCLES_FU_LL.PEER_PROBE_TRACKER      | Uncore cycles Global Queue peer probe tracker is full. The peer probe tracker queue tracks snoops from the IOH and remote sockets.                 |         |
| 01H        | 01H         | UNC_GQ_CYCLES_NO_T_EMPTY.READ_TRACKER       | Uncore cycles were Global Queue read tracker has at least one valid entry.                                                                         |         |
| 01H        | 02H         | UNC_GQ_CYCLES_NO_T_EMPTY.WRITE_TRACKER      | Uncore cycles were Global Queue write tracker has at least one valid entry.                                                                        |         |
| 01H        | 04H         | UNC_GQ_CYCLES_NO_T_EMPTY.PEER_PROBE_TRACKER | Uncore cycles were Global Queue peer probe tracker has at least one valid entry. The peer probe tracker queue tracks IOH and remote socket snoops. |         |

**Table A-7. Non-Architectural Performance Events In the Processor Uncore for Processors Based on Intel Microarchitecture Code Name Westmere**

| Event Num. | Umask Value | Event Mask Mnemonic           | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            | Comment |
|------------|-------------|-------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------|
| 02H        | 01H         | UNC_GQ_OCCUPANCY.READ_TRACKER | Increments the number of queue entries (code read, data read, and RFOs) in the tread tracker. The GQ read tracker allocate to deallocate occupancy count is divided by the count to obtain the average read tracker latency.                                                                                                                                                                                                                                                                                                                           |         |
| 03H        | 01H         | UNC_GQ_ALLOC.READ_TRACKER     | Counts the number of tread tracker allocate to deallocate entries. The GQ read tracker allocate to deallocate occupancy count is divided by the count to obtain the average read tracker latency.                                                                                                                                                                                                                                                                                                                                                      |         |
| 03H        | 02H         | UNC_GQ_ALLOC.RT_L3_MISS       | Counts the number GQ read tracker entries for which a full cache line read has missed the L3. The GQ read tracker L3 miss to fill occupancy count is divided by this count to obtain the average cache line read L3 miss latency. The latency represents the time after which the L3 has determined that the cache line has missed. The time between a GQ read tracker allocation and the L3 determining that the cache line has missed is the average L3 hit latency. The total L3 cache line read miss latency is the hit latency + L3 miss latency. |         |
| 03H        | 04H         | UNC_GQ_ALLOC.RT_TO_L3_RESP    | Counts the number of GQ read tracker entries that are allocated in the read tracker queue that hit or miss the L3. The GQ read tracker L3 hit occupancy count is divided by this count to obtain the average L3 hit latency.                                                                                                                                                                                                                                                                                                                           |         |

## PERFORMANCE-MONITORING EVENTS

**Table A-7. Non-Architectural Performance Events In the Processor Uncore for Processors Based on Intel Microarchitecture Code Name Westmere**

| Event Num. | Umask Value | Event Mask Mnemonic              | Description                                                                                                                                                                                                                                                                                                           | Comment |
|------------|-------------|----------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------|
| 03H        | 08H         | UNC_GQ_ALLOC.RT_TO_RTID_ACQUIRED | Counts the number of GQ read tracker entries that are allocated in the read tracker, have missed in the L3 and have not acquired a Request Transaction ID. The GQ read tracker L3 miss to RTID acquired occupancy count is divided by this count to obtain the average latency for a read L3 miss to acquire an RTID. |         |
| 03H        | 10H         | UNC_GQ_ALLOC.WT_TO_RTID_ACQUIRED | Counts the number of GQ write tracker entries that are allocated in the write tracker, have missed in the L3 and have not acquired a Request Transaction ID. The GQ write tracker L3 miss to RTID occupancy count is divided by this count to obtain the average latency for a write L3 miss to acquire an RTID.      |         |
| 03H        | 20H         | UNC_GQ_ALLOC.WRITE_TRACKER       | Counts the number of GQ write tracker entries that are allocated in the write tracker queue that miss the L3. The GQ write tracker occupancy count is divided by this count to obtain the average L3 write miss latency.                                                                                              |         |
| 03H        | 40H         | UNC_GQ_ALLOC.PEER_PROBE_TRACKER  | Counts the number of GQ peer probe tracker (snoop) entries that are allocated in the peer probe tracker queue that miss the L3. The GQ peer probe occupancy count is divided by this count to obtain the average L3 peer probe miss latency.                                                                          |         |
| 04H        | 01H         | UNC_GQ_DATA.FROM_QPI             | Cycles Global Queue Quickpath Interface input data port is busy importing data from the Quickpath Interface. Each cycle the input port can transfer 8 or 16 bytes of data.                                                                                                                                            |         |

**Table A-7. Non-Architectural Performance Events In the Processor Uncore for Processors Based on Intel Microarchitecture Code Name Westmere**

| Event Num. | Umask Value | Event Mask Mnemonic                 | Description                                                                                                                                                                              | Comment |
|------------|-------------|-------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------|
| 04H        | 02H         | UNC_GQ_DATA.FROM_QMC                | Cycles Global Queue Quickpath Memory Interface input data port is busy importing data from the Quickpath Memory Interface. Each cycle the input port can transfer 8 or 16 bytes of data. |         |
| 04H        | 04H         | UNC_GQ_DATA.FROM_L3                 | Cycles GQ L3 input data port is busy importing data from the Last Level Cache. Each cycle the input port can transfer 32 bytes of data.                                                  |         |
| 04H        | 08H         | UNC_GQ_DATA.FROM_CORES_02           | Cycles GQ Core 0 and 2 input data port is busy importing data from processor cores 0 and 2. Each cycle the input port can transfer 32 bytes of data.                                     |         |
| 04H        | 10H         | UNC_GQ_DATA.FROM_CORES_13           | Cycles GQ Core 1 and 3 input data port is busy importing data from processor cores 1 and 3. Each cycle the input port can transfer 32 bytes of data.                                     |         |
| 05H        | 01H         | UNC_GQ_DATA.TO_QPI_QMC              | Cycles GQ QPI and QMC output data port is busy sending data to the Quickpath Interface or Quickpath Memory Interface. Each cycle the output port can transfer 32 bytes of data.          |         |
| 05H        | 02H         | UNC_GQ_DATA.TO_L3                   | Cycles GQ L3 output data port is busy sending data to the Last Level Cache. Each cycle the output port can transfer 32 bytes of data.                                                    |         |
| 05H        | 04H         | UNC_GQ_DATA.TO_CORES                | Cycles GQ Core output data port is busy sending data to the Cores. Each cycle the output port can transfer 32 bytes of data.                                                             |         |
| 06H        | 01H         | UNC_SNP_RESP_TO_LOCAL_HOME.I_STAT_E | Number of snoop responses to the local home that L3 does not have the referenced cache line.                                                                                             |         |

## PERFORMANCE-MONITORING EVENTS

**Table A-7. Non-Architectural Performance Events In the Processor Uncore for Processors Based on Intel Microarchitecture Code Name Westmere**

| Event Num. | Umask Value | Event Mask Mnemonic                     | Description                                                                                                                                                                                                                               | Comment |
|------------|-------------|-----------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------|
| 06H        | 02H         | UNC_SNP_RESP_TO_LOCAL_HOME.S_STATE      | Number of snoop responses to the local home that L3 has the referenced line cached in the S state.                                                                                                                                        |         |
| 06H        | 04H         | UNC_SNP_RESP_TO_LOCAL_HOME.FWD_S_STATE  | Number of responses to code or data read snoops to the local home that the L3 has the referenced cache line in the E state. The L3 cache line state is changed to the S state and the line is forwarded to the local home in the S state. |         |
| 06H        | 08H         | UNC_SNP_RESP_TO_LOCAL_HOME.FWD_I_STATE  | Number of responses to read invalidate snoops to the local home that the L3 has the referenced cache line in the M state. The L3 cache line state is invalidated and the line is forwarded to the local home in the M state.              |         |
| 06H        | 10H         | UNC_SNP_RESP_TO_LOCAL_HOME.CONFLICT     | Number of conflict snoop responses sent to the local home.                                                                                                                                                                                |         |
| 06H        | 20H         | UNC_SNP_RESP_TO_LOCAL_HOME.WB           | Number of responses to code or data read snoops to the local home that the L3 has the referenced line cached in the M state.                                                                                                              |         |
| 07H        | 01H         | UNC_SNP_RESP_TO_REMOTE_HOME.I_STATE     | Number of snoop responses to a remote home that L3 does not have the referenced cache line.                                                                                                                                               |         |
| 07H        | 02H         | UNC_SNP_RESP_TO_REMOTE_HOME.S_STATE     | Number of snoop responses to a remote home that L3 has the referenced line cached in the S state.                                                                                                                                         |         |
| 07H        | 04H         | UNC_SNP_RESP_TO_REMOTE_HOME.FWD_S_STATE | Number of responses to code or data read snoops to a remote home that the L3 has the referenced cache line in the E state. The L3 cache line state is changed to the S state and the line is forwarded to the remote home in the S state. |         |

**Table A-7. Non-Architectural Performance Events In the Processor Uncore for Processors Based on Intel Microarchitecture Code Name Westmere**

| Event Num. | Umask Value | Event Mask Mnemonic                     | Description                                                                                                                                                                                                                    | Comment |
|------------|-------------|-----------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------|
| 07H        | 08H         | UNC_SNP_RESP_TO_REMOTE_HOME.FWD_I_STATE | Number of responses to read invalidation snoops to a remote home that the L3 has the referenced cache line in the M state. The L3 cache line state is invalidated and the line is forwarded to the remote home in the M state. |         |
| 07H        | 10H         | UNC_SNP_RESP_TO_REMOTE_HOME.CONFLICT    | Number of conflict snoop responses sent to the local home.                                                                                                                                                                     |         |
| 07H        | 20H         | UNC_SNP_RESP_TO_REMOTE_HOME.WB          | Number of responses to code or data read snoops to a remote home that the L3 has the referenced line cached in the M state.                                                                                                    |         |
| 07H        | 24H         | UNC_SNP_RESP_TO_REMOTE_HOME.HITM        | Number of HITM snoop responses to a remote home                                                                                                                                                                                |         |
| 08H        | 01H         | UNC_L3_HITS.READ                        | Number of code read, data read and RFO requests that hit in the L3                                                                                                                                                             |         |
| 08H        | 02H         | UNC_L3_HITS.WRITE                       | Number of writeback requests that hit in the L3. Writebacks from the cores will always result in L3 hits due to the inclusive property of the L3.                                                                              |         |
| 08H        | 04H         | UNC_L3_HITS.PROBE                       | Number of snoops from IOH or remote sockets that hit in the L3.                                                                                                                                                                |         |
| 08H        | 03H         | UNC_L3_HITS.ANY                         | Number of reads and writes that hit the L3.                                                                                                                                                                                    |         |
| 09H        | 01H         | UNC_L3_MISS.READ                        | Number of code read, data read and RFO requests that miss the L3.                                                                                                                                                              |         |
| 09H        | 02H         | UNC_L3_MISS.WRITE                       | Number of writeback requests that miss the L3. Should always be zero as writebacks from the cores will always result in L3 hits due to the inclusive property of the L3.                                                       |         |
| 09H        | 04H         | UNC_L3_MISS.PROBE                       | Number of snoops from IOH or remote sockets that miss the L3.                                                                                                                                                                  |         |
| 09H        | 03H         | UNC_L3_MISS.ANY                         | Number of reads and writes that miss the L3.                                                                                                                                                                                   |         |

## PERFORMANCE-MONITORING EVENTS

**Table A-7. Non-Architectural Performance Events In the Processor Uncore for Processors Based on Intel Microarchitecture Code Name Westmere**

| Event Num. | Umask Value | Event Mask Mnemonic      | Description                                                                                                                                                                                                   | Comment |
|------------|-------------|--------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------|
| 0AH        | 01H         | UNC_L3_LINES_IN.M_STATE  | Counts the number of L3 lines allocated in M state. The only time a cache line is allocated in the M state is when the line was forwarded in M state is forwarded due to a Snoop Read Invalidate Own request. |         |
| 0AH        | 02H         | UNC_L3_LINES_IN.E_STATE  | Counts the number of L3 lines allocated in E state.                                                                                                                                                           |         |
| 0AH        | 04H         | UNC_L3_LINES_IN.S_STATE  | Counts the number of L3 lines allocated in S state.                                                                                                                                                           |         |
| 0AH        | 08H         | UNC_L3_LINES_IN.F_STATE  | Counts the number of L3 lines allocated in F state.                                                                                                                                                           |         |
| 0AH        | 0FH         | UNC_L3_LINES_IN.ANY      | Counts the number of L3 lines allocated in any state.                                                                                                                                                         |         |
| 0BH        | 01H         | UNC_L3_LINES_OUT.M_STATE | Counts the number of L3 lines victimized that were in the M state. When the victim cache line is in M state, the line is written to its home cache agent which can be either local or remote.                 |         |
| 0BH        | 02H         | UNC_L3_LINES_OUT.E_STATE | Counts the number of L3 lines victimized that were in the E state.                                                                                                                                            |         |
| 0BH        | 04H         | UNC_L3_LINES_OUT.S_STATE | Counts the number of L3 lines victimized that were in the S state.                                                                                                                                            |         |
| 0BH        | 08H         | UNC_L3_LINES_OUT.I_STATE | Counts the number of L3 lines victimized that were in the I state.                                                                                                                                            |         |
| 0BH        | 10H         | UNC_L3_LINES_OUT.F_STATE | Counts the number of L3 lines victimized that were in the F state.                                                                                                                                            |         |
| 0BH        | 1FH         | UNC_L3_LINES_OUT.ANY     | Counts the number of L3 lines victimized in any state.                                                                                                                                                        |         |
| 0CH        | 01H         | UNC_GQ_SNOOP.GOT_O_S     | Counts the number of remote snoops that have requested a cache line be set to the S state.                                                                                                                    |         |
| 0CH        | 02H         | UNC_GQ_SNOOP.GOT_O_I     | Counts the number of remote snoops that have requested a cache line be set to the I state.                                                                                                                    |         |

**Table A-7. Non-Architectural Performance Events In the Processor Uncore for Processors Based on Intel Microarchitecture Code Name Westmere**

| Event Num. | Umask Value | Event Mask Mnemonic            | Description                                                                                                       | Comment                                  |
|------------|-------------|--------------------------------|-------------------------------------------------------------------------------------------------------------------|------------------------------------------|
| OCH        | 04H         | UNC_GQ_SNOOP.GOT_O_S_HIT_E     | Counts the number of remote snoops that have requested a cache line be set to the S state from E state.           | Requires writing MSR 301H with mask = 2H |
| OCH        | 04H         | UNC_GQ_SNOOP.GOT_O_S_HIT_F     | Counts the number of remote snoops that have requested a cache line be set to the S state from F (forward) state. | Requires writing MSR 301H with mask = 8H |
| OCH        | 04H         | UNC_GQ_SNOOP.GOT_O_S_HIT_M     | Counts the number of remote snoops that have requested a cache line be set to the S state from M state.           | Requires writing MSR 301H with mask = 1H |
| OCH        | 04H         | UNC_GQ_SNOOP.GOT_O_S_HIT_S     | Counts the number of remote snoops that have requested a cache line be set to the S state from S state.           | Requires writing MSR 301H with mask = 4H |
| OCH        | 08H         | UNC_GQ_SNOOP.GOT_O_I_HIT_E     | Counts the number of remote snoops that have requested a cache line be set to the I state from E state.           | Requires writing MSR 301H with mask = 2H |
| OCH        | 08H         | UNC_GQ_SNOOP.GOT_O_I_HIT_F     | Counts the number of remote snoops that have requested a cache line be set to the I state from F (forward) state. | Requires writing MSR 301H with mask = 8H |
| OCH        | 08H         | UNC_GQ_SNOOP.GOT_O_I_HIT_M     | Counts the number of remote snoops that have requested a cache line be set to the I state from M state.           | Requires writing MSR 301H with mask = 1H |
| OCH        | 08H         | UNC_GQ_SNOOP.GOT_O_I_HIT_S     | Counts the number of remote snoops that have requested a cache line be set to the I state from S state.           | Requires writing MSR 301H with mask = 4H |
| 20H        | 01H         | UNC_QHL_REQUEST_S.IOH_READS    | Counts number of Quickpath Home Logic read requests from the IOH.                                                 |                                          |
| 20H        | 02H         | UNC_QHL_REQUEST_S.IOH_WRITES   | Counts number of Quickpath Home Logic write requests from the IOH.                                                |                                          |
| 20H        | 04H         | UNC_QHL_REQUEST_S.REMOTE_READS | Counts number of Quickpath Home Logic read requests from a remote socket.                                         |                                          |

## PERFORMANCE-MONITORING EVENTS

**Table A-7. Non-Architectural Performance Events In the Processor Uncore for Processors Based on Intel Microarchitecture Code Name Westmere**

| Event Num. | Umask Value | Event Mask Mnemonic             | Description                                                                         | Comment |
|------------|-------------|---------------------------------|-------------------------------------------------------------------------------------|---------|
| 20H        | 08H         | UNC_QHL_REQUEST_S.REMOTE_WRITES | Counts number of Quickpath Home Logic write requests from a remote socket.          |         |
| 20H        | 10H         | UNC_QHL_REQUEST_S.LOCAL_READS   | Counts number of Quickpath Home Logic read requests from the local socket.          |         |
| 20H        | 20H         | UNC_QHL_REQUEST_S.LOCAL_WRITES  | Counts number of Quickpath Home Logic write requests from the local socket.         |         |
| 21H        | 01H         | UNC_QHL_CYCLES_FULLLIOH         | Counts uclk cycles all entries in the Quickpath Home Logic IOH are full.            |         |
| 21H        | 02H         | UNC_QHL_CYCLES_FULL.REMOTE      | Counts uclk cycles all entries in the Quickpath Home Logic remote tracker are full. |         |
| 21H        | 04H         | UNC_QHL_CYCLES_FULL.LOCAL       | Counts uclk cycles all entries in the Quickpath Home Logic local tracker are full.  |         |
| 22H        | 01H         | UNC_QHL_CYCLES_NOT_EMPTY.IOH    | Counts uclk cycles all entries in the Quickpath Home Logic IOH is busy.             |         |
| 22H        | 02H         | UNC_QHL_CYCLES_NOT_EMPTY.REMOTE | Counts uclk cycles all entries in the Quickpath Home Logic remote tracker is busy.  |         |
| 22H        | 04H         | UNC_QHL_CYCLES_NOT_EMPTY.LOCAL  | Counts uclk cycles all entries in the Quickpath Home Logic local tracker is busy.   |         |
| 23H        | 01H         | UNC_QHL_OCCUPANCY.IOH           | QHL IOH tracker allocate to deallocate read occupancy.                              |         |
| 23H        | 02H         | UNC_QHL_OCCUPANCY.REMOTE        | QHL remote tracker allocate to deallocate read occupancy.                           |         |
| 23H        | 04H         | UNC_QHL_OCCUPANCY.LOCAL         | QHL local tracker allocate to deallocate read occupancy.                            |         |

**Table A-7. Non-Architectural Performance Events In the Processor Uncore for Processors Based on Intel Microarchitecture Code Name Westmere**

| Event Num. | Umask Value | Event Mask Mnemonic            | Description                                                                                                                                                                                                                                                            | Comment |
|------------|-------------|--------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------|
| 24H        | 02H         | UNC_QHL_ADDRESS_CONFLICTS.2WAY | Counts number of QHL Active Address Table (AAT) entries that saw a max of 2 conflicts. The AAT is a structure that tracks requests that are in conflict. The requests themselves are in the home tracker entries. The count is reported when an AAT entry deallocates. |         |
| 24H        | 04H         | UNC_QHL_ADDRESS_CONFLICTS.3WAY | Counts number of QHL Active Address Table (AAT) entries that saw a max of 3 conflicts. The AAT is a structure that tracks requests that are in conflict. The requests themselves are in the home tracker entries. The count is reported when an AAT entry deallocates. |         |
| 25H        | 01H         | UNC_QHL_CONFLICT_CYCLES.IOH    | Counts cycles the Quickpath Home Logic IOH Tracker contains two or more requests with an address conflict. A max of 3 requests can be in conflict.                                                                                                                     |         |
| 25H        | 02H         | UNC_QHL_CONFLICT_CYCLES.REMOTE | Counts cycles the Quickpath Home Logic Remote Tracker contains two or more requests with an address conflict. A max of 3 requests can be in conflict.                                                                                                                  |         |
| 25H        | 04H         | UNC_QHL_CONFLICT_CYCLES.LOCAL  | Counts cycles the Quickpath Home Logic Local Tracker contains two or more requests with an address conflict. A max of 3 requests can be in conflict.                                                                                                                   |         |
| 26H        | 01H         | UNC_QHL_TO_QMC_BYPASS          | Counts number of requests to the Quickpath Memory Controller that bypass the Quickpath Home Logic. All local accesses can be bypassed. For remote requests, only read requests can be bypassed.                                                                        |         |

## PERFORMANCE-MONITORING EVENTS

**Table A-7. Non-Architectural Performance Events In the Processor Uncore for Processors Based on Intel Microarchitecture Code Name Westmere**

| Event Num. | Umask Value | Event Mask Mnemonic          | Description                                                                                                           | Comment |
|------------|-------------|------------------------------|-----------------------------------------------------------------------------------------------------------------------|---------|
| 28H        | 01H         | UNC_QMC_ISOC_FUL.L.READ.CHO  | Counts cycles all the entries in the DRAM channel 0 high priority queue are occupied with isochronous read requests.  |         |
| 28H        | 02H         | UNC_QMC_ISOC_FUL.L.READ.CH1  | Counts cycles all the entries in the DRAM channel 1 high priority queue are occupied with isochronous read requests.  |         |
| 28H        | 04H         | UNC_QMC_ISOC_FUL.L.READ.CH2  | Counts cycles all the entries in the DRAM channel 2 high priority queue are occupied with isochronous read requests.  |         |
| 28H        | 08H         | UNC_QMC_ISOC_FUL.L.WRITE.CHO | Counts cycles all the entries in the DRAM channel 0 high priority queue are occupied with isochronous write requests. |         |
| 28H        | 10H         | UNC_QMC_ISOC_FUL.L.WRITE.CH1 | Counts cycles all the entries in the DRAM channel 1 high priority queue are occupied with isochronous write requests. |         |
| 28H        | 20H         | UNC_QMC_ISOC_FUL.L.WRITE.CH2 | Counts cycles all the entries in the DRAM channel 2 high priority queue are occupied with isochronous write requests. |         |
| 29H        | 01H         | UNC_QMC_BUSY.REA.D.CHO       | Counts cycles where Quickpath Memory Controller has at least 1 outstanding read request to DRAM channel 0.            |         |
| 29H        | 02H         | UNC_QMC_BUSY.REA.D.CH1       | Counts cycles where Quickpath Memory Controller has at least 1 outstanding read request to DRAM channel 1.            |         |
| 29H        | 04H         | UNC_QMC_BUSY.REA.D.CH2       | Counts cycles where Quickpath Memory Controller has at least 1 outstanding read request to DRAM channel 2.            |         |

**Table A-7. Non-Architectural Performance Events In the Processor Uncore for Processors Based on Intel Microarchitecture Code Name Westmere**

| Event Num. | Umask Value | Event Mask Mnemonic         | Description                                                                                                                                                                                                      | Comment |
|------------|-------------|-----------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------|
| 29H        | 08H         | UNC_QMC_BUSY.WR1TE.CHO      | Counts cycles where Quickpath Memory Controller has at least 1 outstanding write request to DRAM channel 0.                                                                                                      |         |
| 29H        | 10H         | UNC_QMC_BUSY.WR1TE.CH1      | Counts cycles where Quickpath Memory Controller has at least 1 outstanding write request to DRAM channel 1.                                                                                                      |         |
| 29H        | 20H         | UNC_QMC_BUSY.WR1TE.CH2      | Counts cycles where Quickpath Memory Controller has at least 1 outstanding write request to DRAM channel 2.                                                                                                      |         |
| 2AH        | 01H         | UNC_QMC_OCCUPANCY.CHO       | IMC channel 0 normal read request occupancy.                                                                                                                                                                     |         |
| 2AH        | 02H         | UNC_QMC_OCCUPANCY.CH1       | IMC channel 1 normal read request occupancy.                                                                                                                                                                     |         |
| 2AH        | 04H         | UNC_QMC_OCCUPANCY.CH2       | IMC channel 2 normal read request occupancy.                                                                                                                                                                     |         |
| 2AH        | 07H         | UNC_QMC_OCCUPANCY.ANY       | Normal read request occupancy for any channel.                                                                                                                                                                   |         |
| 2BH        | 01H         | UNC_QMC_ISSOC_OCCUPANCY.CHO | IMC channel 0 issoc read request occupancy.                                                                                                                                                                      |         |
| 2BH        | 02H         | UNC_QMC_ISSOC_OCCUPANCY.CH1 | IMC channel 1 issoc read request occupancy.                                                                                                                                                                      |         |
| 2BH        | 04H         | UNC_QMC_ISSOC_OCCUPANCY.CH2 | IMC channel 2 issoc read request occupancy.                                                                                                                                                                      |         |
| 2BH        | 07H         | UNC_QMC_ISSOC_READS.ANY     | IMC issoc read request occupancy.                                                                                                                                                                                |         |
| 2CH        | 01H         | UNC_QMC_NORMAL_READS.CHO    | Counts the number of Quickpath Memory Controller channel 0 medium and low priority read requests. The QMC channel 0 normal read occupancy divided by this count provides the average QMC channel 0 read latency. |         |

## PERFORMANCE-MONITORING EVENTS

**Table A-7. Non-Architectural Performance Events In the Processor Uncore for Processors Based on Intel Microarchitecture Code Name Westmere**

| Event Num. | Umask Value | Event Mask Mnemonic                 | Description                                                                                                                                                                                                      | Comment |
|------------|-------------|-------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------|
| 2CH        | 02H         | UNC_QMC_NORMAL_READS.CH1            | Counts the number of Quickpath Memory Controller channel 1 medium and low priority read requests. The QMC channel 1 normal read occupancy divided by this count provides the average QMC channel 1 read latency. |         |
| 2CH        | 04H         | UNC_QMC_NORMAL_READS.CH2            | Counts the number of Quickpath Memory Controller channel 2 medium and low priority read requests. The QMC channel 2 normal read occupancy divided by this count provides the average QMC channel 2 read latency. |         |
| 2CH        | 07H         | UNC_QMC_NORMAL_READS.ANY            | Counts the number of Quickpath Memory Controller medium and low priority read requests. The QMC normal read occupancy divided by this count provides the average QMC read latency.                               |         |
| 2DH        | 01H         | UNC_QMC_HIGH_PRIORITY_READS.CH0     | Counts the number of Quickpath Memory Controller channel 0 high priority isochronous read requests.                                                                                                              |         |
| 2DH        | 02H         | UNC_QMC_HIGH_PRIORITY_READS.CH1     | Counts the number of Quickpath Memory Controller channel 1 high priority isochronous read requests.                                                                                                              |         |
| 2DH        | 04H         | UNC_QMC_HIGH_PRIORITY_READS.CH2     | Counts the number of Quickpath Memory Controller channel 2 high priority isochronous read requests.                                                                                                              |         |
| 2DH        | 07H         | UNC_QMC_HIGH_PRIORITY_READS.ANY     | Counts the number of Quickpath Memory Controller high priority isochronous read requests.                                                                                                                        |         |
| 2EH        | 01H         | UNC_QMC_CRITICAL_PRIORITY_READS.CH0 | Counts the number of Quickpath Memory Controller channel 0 critical priority isochronous read requests.                                                                                                          |         |
| 2EH        | 02H         | UNC_QMC_CRITICAL_PRIORITY_READS.CH1 | Counts the number of Quickpath Memory Controller channel 1 critical priority isochronous read requests.                                                                                                          |         |

**Table A-7. Non-Architectural Performance Events In the Processor Uncore for Processors Based on Intel Microarchitecture Code Name Westmere**

| Event Num. | Umask Value | Event Mask Mnemonic                 | Description                                                                                             | Comment |
|------------|-------------|-------------------------------------|---------------------------------------------------------------------------------------------------------|---------|
| 2EH        | 04H         | UNC_QMC_CRITICAL_PRIORITY_READS.CH2 | Counts the number of Quickpath Memory Controller channel 2 critical priority isochronous read requests. |         |
| 2EH        | 07H         | UNC_QMC_CRITICAL_PRIORITY_READS.ANY | Counts the number of Quickpath Memory Controller critical priority isochronous read requests.           |         |
| 2FH        | 01H         | UNC_QMC_WRITES.FULLL.CHO            | Counts number of full cache line writes to DRAM channel 0.                                              |         |
| 2FH        | 02H         | UNC_QMC_WRITES.FULLL.CH1            | Counts number of full cache line writes to DRAM channel 1.                                              |         |
| 2FH        | 04H         | UNC_QMC_WRITES.FULLL.CH2            | Counts number of full cache line writes to DRAM channel 2.                                              |         |
| 2FH        | 07H         | UNC_QMC_WRITES.FULLL.ANY            | Counts number of full cache line writes to DRAM.                                                        |         |
| 2FH        | 08H         | UNC_QMC_WRITES.PARTIAL.CHO          | Counts number of partial cache line writes to DRAM channel 0.                                           |         |
| 2FH        | 10H         | UNC_QMC_WRITES.PARTIAL.CH1          | Counts number of partial cache line writes to DRAM channel 1.                                           |         |
| 2FH        | 20H         | UNC_QMC_WRITES.PARTIAL.CH2          | Counts number of partial cache line writes to DRAM channel 2.                                           |         |
| 2FH        | 38H         | UNC_QMC_WRITES.PARTIAL.ANY          | Counts number of partial cache line writes to DRAM.                                                     |         |
| 30H        | 01H         | UNC_QMC_CANCEL.CHO                  | Counts number of DRAM channel 0 cancel requests.                                                        |         |
| 30H        | 02H         | UNC_QMC_CANCEL.CH1                  | Counts number of DRAM channel 1 cancel requests.                                                        |         |
| 30H        | 04H         | UNC_QMC_CANCEL.CH2                  | Counts number of DRAM channel 2 cancel requests.                                                        |         |
| 30H        | 07H         | UNC_QMC_CANCEL.ANY                  | Counts number of DRAM cancel requests.                                                                  |         |

## PERFORMANCE-MONITORING EVENTS

**Table A-7. Non-Architectural Performance Events In the Processor Uncore for Processors Based on Intel Microarchitecture Code Name Westmere**

| Event Num. | Umask Value | Event Mask Mnemonic          | Description                                                                                                                                                                                                                                                                                                                 | Comment |
|------------|-------------|------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------|
| 31H        | 01H         | UNC_QMC_PRIORITY_UPDATES.CH0 | Counts number of DRAM channel 0 priority updates. A priority update occurs when an ISOC high or critical request is received by the QHL and there is a matching request with normal priority that has already been issued to the QMC. In this instance, the QHL will send a priority update to QMC to expedite the request. |         |
| 31H        | 02H         | UNC_QMC_PRIORITY_UPDATES.CH1 | Counts number of DRAM channel 1 priority updates. A priority update occurs when an ISOC high or critical request is received by the QHL and there is a matching request with normal priority that has already been issued to the QMC. In this instance, the QHL will send a priority update to QMC to expedite the request. |         |
| 31H        | 04H         | UNC_QMC_PRIORITY_UPDATES.CH2 | Counts number of DRAM channel 2 priority updates. A priority update occurs when an ISOC high or critical request is received by the QHL and there is a matching request with normal priority that has already been issued to the QMC. In this instance, the QHL will send a priority update to QMC to expedite the request. |         |
| 31H        | 07H         | UNC_QMC_PRIORITY_UPDATES.ANY | Counts number of DRAM priority updates. A priority update occurs when an ISOC high or critical request is received by the QHL and there is a matching request with normal priority that has already been issued to the QMC. In this instance, the QHL will send a priority update to QMC to expedite the request.           |         |
| 32H        | 01H         | UNC_IMC_RETRY.CH0            | Counts number of IMC DRAM channel 0 retries. DRAM retry only occurs when configured in RAS mode.                                                                                                                                                                                                                            |         |

**Table A-7. Non-Architectural Performance Events In the Processor Uncore for Processors Based on Intel Microarchitecture Code Name Westmere**

| Event Num. | Umask Value | Event Mask Mnemonic           | Description                                                                                                                                                                                           | Comment |
|------------|-------------|-------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------|
| 32H        | 02H         | UNC_IMC_RETRY.CH 1            | Counts number of IMC DRAM channel 1 retries. DRAM retry only occurs when configured in RAS mode.                                                                                                      |         |
| 32H        | 04H         | UNC_IMC_RETRY.CH 2            | Counts number of IMC DRAM channel 2 retries. DRAM retry only occurs when configured in RAS mode.                                                                                                      |         |
| 32H        | 07H         | UNC_IMC_RETRY.ANY             | Counts number of IMC DRAM retries from any channel. DRAM retry only occurs when configured in RAS mode.                                                                                               |         |
| 33H        | 01H         | UNC_QHL_FRC_ACK_CNFLTS.IOH    | Counts number of Force Acknowledge Conflict messages sent by the Quickpath Home Logic to the IOH.                                                                                                     |         |
| 33H        | 02H         | UNC_QHL_FRC_ACK_CNFLTS.REMOTE | Counts number of Force Acknowledge Conflict messages sent by the Quickpath Home Logic to the remote home.                                                                                             |         |
| 33H        | 04H         | UNC_QHL_FRC_ACK_CNFLTS.LOCAL  | Counts number of Force Acknowledge Conflict messages sent by the Quickpath Home Logic to the local home.                                                                                              |         |
| 33H        | 07H         | UNC_QHL_FRC_ACK_CNFLTS.ANY    | Counts number of Force Acknowledge Conflict messages sent by the Quickpath Home Logic.                                                                                                                |         |
| 34H        | 01H         | UNC_QHL_SLEEP.IOH_ORDER       | Counts number of occurrences a request was put to sleep due to IOH ordering (write after read) conflicts. While in the sleep state, the request is not eligible to be scheduled to the QMC.           |         |
| 34H        | 02H         | UNC_QHL_SLEEP.REMOTE_ORDER    | Counts number of occurrences a request was put to sleep due to remote socket ordering (write after read) conflicts. While in the sleep state, the request is not eligible to be scheduled to the QMC. |         |

## PERFORMANCE-MONITORING EVENTS

**Table A-7. Non-Architectural Performance Events In the Processor Uncore for Processors Based on Intel Microarchitecture Code Name Westmere**

| Event Num. | Umask Value | Event Mask Mnemonic            | Description                                                                                                                                                                                                                                                    | Comment                                                                   |
|------------|-------------|--------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------|
| 34H        | 04H         | UNC_QHL_SLEEPS.LOCAL_ORDER     | Counts number of occurrences a request was put to sleep due to local socket ordering (write after read) conflicts. While in the sleep state, the request is not eligible to be scheduled to the QMC.                                                           |                                                                           |
| 34H        | 08H         | UNC_QHL_SLEEPS.IOH_CONFLICT    | Counts number of occurrences a request was put to sleep due to IOH address conflicts. While in the sleep state, the request is not eligible to be scheduled to the QMC.                                                                                        |                                                                           |
| 34H        | 10H         | UNC_QHL_SLEEPS.REMOTE_CONFLICT | Counts number of occurrences a request was put to sleep due to remote socket address conflicts. While in the sleep state, the request is not eligible to be scheduled to the QMC.                                                                              |                                                                           |
| 34H        | 20H         | UNC_QHL_SLEEPS.LOCAL_CONFLICT  | Counts number of occurrences a request was put to sleep due to local socket address conflicts. While in the sleep state, the request is not eligible to be scheduled to the QMC.                                                                               |                                                                           |
| 35H        | 01H         | UNC_ADDR_OPCODE_MATCH.IOH      | Counts number of requests from the IOH, address/opcode of request is qualified by mask value written to MSR 396H. The following mask values are supported:<br>0: NONE<br>40000000_00000000H:RSPFWDI<br>40001A00_00000000H:RSPFWDS<br>40001D00_00000000H:RSPIWB | Match opcode/addresses by writing MSR 396H with mask supported mask value |

| 41H        | 01H         | UNC_QPI_TX_STALL<br>ED_MULTI_FLIT.DRS.<br>LINK_0 | Counts cycles the Quickpath outbound link 0 Data ResponSe virtual channel is stalled due to lack of VNA and VNO credits. Note that this event does not filter out when a flit would not have been selected for arbitration because another virtual channel is getting arbitrated.         |         |
| 41H        | 02H         | UNC_QPI_TX_STALL<br>ED_MULTI_FLIT.NCB.<br>LINK_0 | Counts cycles the Quickpath outbound link 0 Non-Coherent Bypass virtual channel is stalled due to lack of VNA and VNO credits. Note that this event does not filter out when a flit would not have been selected for arbitration because another virtual channel is getting arbitrated.   |         |
| 41H        | 04H         | UNC_QPI_TX_STALL<br>ED_MULTI_FLIT.NCS.<br>LINK_0 | Counts cycles the Quickpath outbound link 0 Non-Coherent Standard virtual channel is stalled due to lack of VNA and VNO credits. Note that this event does not filter out when a flit would not have been selected for arbitration because another virtual channel is getting arbitrated. |         |
| 41H        | 08H         | UNC_QPI_TX_STALL<br>ED_MULTI_FLIT.DRS.<br>LINK_1 | Counts cycles the Quickpath outbound link 1 Data ResponSe virtual channel is stalled due to lack of VNA and VNO credits. Note that this event does not filter out when a flit would not have been selected for arbitration because another virtual channel is getting arbitrated.         |         |

## PERFORMANCE-MONITORING EVENTS

**Table A-7. Non-Architectural Performance Events In the Processor Uncore for Processors Based on Intel Microarchitecture Code Name Westmere**

| Event Num. | Umask Value | Event Mask Mnemonic                        | Description                                                                                                                                                                                                                                                                               | Comment |
|------------|-------------|--------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------|
| 41H        | 10H         | UNC_QPI_TX_STALL ED_MULTI_FLIT.NCB. LINK_1 | Counts cycles the Quickpath outbound link 1 Non-Coherent Bypass virtual channel is stalled due to lack of VNA and VNO credits. Note that this event does not filter out when a flit would not have been selected for arbitration because another virtual channel is getting arbitrated.   |         |
| 41H        | 20H         | UNC_QPI_TX_STALL ED_MULTI_FLIT.NCS. LINK_1 | Counts cycles the Quickpath outbound link 1 Non-Coherent Standard virtual channel is stalled due to lack of VNA and VNO credits. Note that this event does not filter out when a flit would not have been selected for arbitration because another virtual channel is getting arbitrated. |         |
| 41H        | 07H         | UNC_QPI_TX_STALL ED_MULTI_FLIT.LINK _0     | Counts cycles the Quickpath outbound link 0 virtual channels are stalled due to lack of VNA and VNO credits. Note that this event does not filter out when a flit would not have been selected for arbitration because another virtual channel is getting arbitrated.                     |         |
| 41H        | 38H         | UNC_QPI_TX_STALL ED_MULTI_FLIT.LINK _1     | Counts cycles the Quickpath outbound link 1 virtual channels are stalled due to lack of VNA and VNO credits. Note that this event does not filter out when a flit would not have been selected for arbitration because another virtual channel is getting arbitrated.                     |         |
| 42H        | 01H         | UNC_QPI_TX_HEADE R.FULL.LINK_0             | Number of cycles that the header buffer in the Quickpath Interface outbound link 0 is full.                                                                                                                                                                                               |         |
| 42H        | 02H         | UNC_QPI_TX_HEADE R.BUSY.LINK_0             | Number of cycles that the header buffer in the Quickpath Interface outbound link 0 is busy.                                                                                                                                                                                               |         |

**Table A-7. Non-Architectural Performance Events In the Processor Uncore for Processors Based on Intel Microarchitecture Code Name Westmere**

| Event Num. | Umask Value | Event Mask Mnemonic                    | Description                                                                                                                                                                                    | Comment |
|------------|-------------|----------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------|
| 42H        | 04H         | UNC_QPI_TX_HEADER.FULLLINK_1           | Number of cycles that the header buffer in the Quickpath Interface outbound link 1 is full.                                                                                                    |         |
| 42H        | 08H         | UNC_QPI_TX_HEADER.BUSYLINK_1           | Number of cycles that the header buffer in the Quickpath Interface outbound link 1 is busy.                                                                                                    |         |
| 43H        | 01H         | UNC_QPI_RX_NO_PPT_CREDIT.STALLS.LINK_0 | Number of cycles that snoop packets incoming to the Quickpath Interface link 0 are stalled and not sent to the GQ because the GQ Peer Probe Tracker (PPT) does not have any available entries. |         |
| 43H        | 02H         | UNC_QPI_RX_NO_PPT_CREDIT.STALLS.LINK_1 | Number of cycles that snoop packets incoming to the Quickpath Interface link 1 are stalled and not sent to the GQ because the GQ Peer Probe Tracker (PPT) does not have any available entries. |         |
| 60H        | 01H         | UNC_DRAM_OPEN.CH0                      | Counts number of DRAM Channel 0 open commands issued either for read or write. To read or write data, the referenced DRAM page must first be opened.                                           |         |
| 60H        | 02H         | UNC_DRAM_OPEN.CH1                      | Counts number of DRAM Channel 1 open commands issued either for read or write. To read or write data, the referenced DRAM page must first be opened.                                           |         |
| 60H        | 04H         | UNC_DRAM_OPEN.CH2                      | Counts number of DRAM Channel 2 open commands issued either for read or write. To read or write data, the referenced DRAM page must first be opened.                                           |         |
| 61H        | 01H         | UNC_DRAM_PAGE_CLOSE.CHO                | DRAM channel 0 command issued to CLOSE a page due to page idle timer expiration. Closing a page is done by issuing a precharge.                                                                |         |

## PERFORMANCE-MONITORING EVENTS

**Table A-7. Non-Architectural Performance Events In the Processor Uncore for Processors Based on Intel Microarchitecture Code Name Westmere**

| Event Num. | Umask Value | Event Mask Mnemonic         | Description                                                                                                                                                                                                                                                                                                                       | Comment |
|------------|-------------|-----------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------|
| 61H        | 02H         | UNC_DRAM_PAGE_C<br>LOSE.CH1 | DRAM channel 1 command issued to CLOSE a page due to page idle timer expiration. Closing a page is done by issuing a precharge.                                                                                                                                                                                                   |         |
| 61H        | 04H         | UNC_DRAM_PAGE_C<br>LOSE.CH2 | DRAM channel 2 command issued to CLOSE a page due to page idle timer expiration. Closing a page is done by issuing a precharge.                                                                                                                                                                                                   |         |
| 62H        | 01H         | UNC_DRAM_PAGE_M<br>ISS.CH0  | Counts the number of precharges (PRE) that were issued to DRAM channel 0 because there was a page miss. A page miss refers to a situation in which a page is currently open and another page from the same bank needs to be opened. The new page experiences a page miss. Closing of the old page is done by issuing a precharge. |         |
| 62H        | 02H         | UNC_DRAM_PAGE_M<br>ISS.CH1  | Counts the number of precharges (PRE) that were issued to DRAM channel 1 because there was a page miss. A page miss refers to a situation in which a page is currently open and another page from the same bank needs to be opened. The new page experiences a page miss. Closing of the old page is done by issuing a precharge. |         |
| 62H        | 04H         | UNC_DRAM_PAGE_M<br>ISS.CH2  | Counts the number of precharges (PRE) that were issued to DRAM channel 2 because there was a page miss. A page miss refers to a situation in which a page is currently open and another page from the same bank needs to be opened. The new page experiences a page miss. Closing of the old page is done by issuing a precharge. |         |
| 63H        | 01H         | UNC_DRAM_READ_C<br>AS.CH0   | Counts the number of times a read CAS command was issued on DRAM channel 0.                                                                                                                                                                                                                                                       |         |

**Table A-7. Non-Architectural Performance Events In the Processor Uncore for Processors Based on Intel Microarchitecture Code Name Westmere**

| Event Num. | Umask Value | Event Mask Mnemonic            | Description                                                                                                                                          | Comment |
|------------|-------------|--------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------|---------|
| 63H        | 02H         | UNC_DRAM_READ_C AS.AUTOPRE_CHO | Counts the number of times a read CAS command was issued on DRAM channel 0 where the command issued used the auto-precharge (auto page close) mode.  |         |
| 63H        | 04H         | UNC_DRAM_READ_C AS.CH1         | Counts the number of times a read CAS command was issued on DRAM channel 1.                                                                          |         |
| 63H        | 08H         | UNC_DRAM_READ_C AS.AUTOPRE_CH1 | Counts the number of times a read CAS command was issued on DRAM channel 1 where the command issued used the auto-precharge (auto page close) mode.  |         |
| 63H        | 10H         | UNC_DRAM_READ_C AS.CH2         | Counts the number of times a read CAS command was issued on DRAM channel 2.                                                                          |         |
| 63H        | 20H         | UNC_DRAM_READ_C AS.AUTOPRE_CH2 | Counts the number of times a read CAS command was issued on DRAM channel 2 where the command issued used the auto-precharge (auto page close) mode.  |         |
| 64H        | 01H         | UNC_DRAM_WRITE_CAS.CHO         | Counts the number of times a write CAS command was issued on DRAM channel 0.                                                                         |         |
| 64H        | 02H         | UNC_DRAM_WRITE_CAS.AUTOPRE_CHO | Counts the number of times a write CAS command was issued on DRAM channel 0 where the command issued used the auto-precharge (auto page close) mode. |         |
| 64H        | 04H         | UNC_DRAM_WRITE_CAS.CH1         | Counts the number of times a write CAS command was issued on DRAM channel 1.                                                                         |         |
| 64H        | 08H         | UNC_DRAM_WRITE_CAS.AUTOPRE_CH1 | Counts the number of times a write CAS command was issued on DRAM channel 1 where the command issued used the auto-precharge (auto page close) mode. |         |

## PERFORMANCE-MONITORING EVENTS

**Table A-7. Non-Architectural Performance Events In the Processor Uncore for Processors Based on Intel Microarchitecture Code Name Westmere**

| Event Num. | Umask Value | Event Mask Mnemonic            | Description                                                                                                                                                                                      | Comment |
|------------|-------------|--------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------|
| 64H        | 10H         | UNC_DRAM_WRITE_CAS.CH2         | Counts the number of times a write CAS command was issued on DRAM channel 2.                                                                                                                     |         |
| 64H        | 20H         | UNC_DRAM_WRITE_CAS.AUTOPRE_CH2 | Counts the number of times a write CAS command was issued on DRAM channel 2 where the command issued used the auto-precharge (auto page close) mode.                                             |         |
| 65H        | 01H         | UNC_DRAM_REFRESH.CH0           | Counts number of DRAM channel 0 refresh commands. DRAM loses data content over time. In order to keep correct data content, the data values have to be refreshed periodically.                   |         |
| 65H        | 02H         | UNC_DRAM_REFRESH.CH1           | Counts number of DRAM channel 1 refresh commands. DRAM loses data content over time. In order to keep correct data content, the data values have to be refreshed periodically.                   |         |
| 65H        | 04H         | UNC_DRAM_REFRESH.CH2           | Counts number of DRAM channel 2 refresh commands. DRAM loses data content over time. In order to keep correct data content, the data values have to be refreshed periodically.                   |         |
| 66H        | 01H         | UNC_DRAM_PRE_ALL.CH0           | Counts number of DRAM Channel 0 precharge-all (PREALL) commands that close all open pages in a rank. PREALL is issued when the DRAM needs to be refreshed or needs to go into a power down mode. |         |
| 66H        | 02H         | UNC_DRAM_PRE_ALL.CH1           | Counts number of DRAM Channel 1 precharge-all (PREALL) commands that close all open pages in a rank. PREALL is issued when the DRAM needs to be refreshed or needs to go into a power down mode. |         |

**Table A-7. Non-Architectural Performance Events In the Processor Uncore for Processors Based on Intel Microarchitecture Code Name Westmere**

| Event Num. | Umask Value | Event Mask Mnemonic                 | Description                                                                                                                                                                                      | Comment |
|------------|-------------|-------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------|
| 66H        | 04H         | UNC_DRAM_PRE_AL_L.CH2               | Counts number of DRAM Channel 2 precharge-all (PREALL) commands that close all open pages in a rank. PREALL is issued when the DRAM needs to be refreshed or needs to go into a power down mode. |         |
| 67H        | 01H         | UNC_DRAM_THERM_AL_THROTTLED         | Uncore cycles DRAM was throttled due to its temperature being above the thermal throttling threshold.                                                                                            |         |
| 80H        | 01H         | UNC_THERMAL_THR_OTTLING_TEMP.CORE_0 | Cycles that the PCU records that core 0 is above the thermal throttling threshold temperature.                                                                                                   |         |
| 80H        | 02H         | UNC_THERMAL_THR_OTTLING_TEMP.CORE_1 | Cycles that the PCU records that core 1 is above the thermal throttling threshold temperature.                                                                                                   |         |
| 80H        | 04H         | UNC_THERMAL_THR_OTTLING_TEMP.CORE_2 | Cycles that the PCU records that core 2 is above the thermal throttling threshold temperature.                                                                                                   |         |
| 80H        | 08H         | UNC_THERMAL_THR_OTTLING_TEMP.CORE_3 | Cycles that the PCU records that core 3 is above the thermal throttling threshold temperature.                                                                                                   |         |
| 81H        | 01H         | UNC_THERMAL_THR_OTTLED_TEMP.CORE_0  | Cycles that the PCU records that core 0 is in the power throttled state due to core's temperature being above the thermal throttling threshold.                                                  |         |
| 81H        | 02H         | UNC_THERMAL_THR_OTTLED_TEMP.CORE_1  | Cycles that the PCU records that core 1 is in the power throttled state due to core's temperature being above the thermal throttling threshold.                                                  |         |
| 81H        | 04H         | UNC_THERMAL_THR_OTTLED_TEMP.CORE_2  | Cycles that the PCU records that core 2 is in the power throttled state due to core's temperature being above the thermal throttling threshold.                                                  |         |
| 81H        | 08H         | UNC_THERMAL_THR_OTTLED_TEMP.CORE_3  | Cycles that the PCU records that core 3 is in the power throttled state due to core's temperature being above the thermal throttling threshold.                                                  |         |

## PERFORMANCE-MONITORING EVENTS

**Table A-7. Non-Architectural Performance Events In the Processor Uncore for Processors Based on Intel Microarchitecture Code Name Westmere**

| Event Num. | Umask Value | Event Mask Mnemonic                   | Description                                                                                                                                           | Comment |
|------------|-------------|---------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------|---------|
| 82H        | 01H         | UNC_PROCHOT_ASSERTION                 | Number of system assertions of PROCHOT indicating the entire processor has exceeded the thermal limit.                                                |         |
| 83H        | 01H         | UNC_THERMAL_THROTTLING_PROCHOT.CORE_0 | Cycles that the PCU records that core 0 is a low power state due to the system asserting PROCHOT the entire processor has exceeded the thermal limit. |         |
| 83H        | 02H         | UNC_THERMAL_THROTTLING_PROCHOT.CORE_1 | Cycles that the PCU records that core 1 is a low power state due to the system asserting PROCHOT the entire processor has exceeded the thermal limit. |         |
| 83H        | 04H         | UNC_THERMAL_THROTTLING_PROCHOT.CORE_2 | Cycles that the PCU records that core 2 is a low power state due to the system asserting PROCHOT the entire processor has exceeded the thermal limit. |         |
| 83H        | 08H         | UNC_THERMAL_THROTTLING_PROCHOT.CORE_3 | Cycles that the PCU records that core 3 is a low power state due to the system asserting PROCHOT the entire processor has exceeded the thermal limit. |         |
| 84H        | 01H         | UNC_TURBO_MODE.CORE_0                 | Uncore cycles that core 0 is operating in turbo mode.                                                                                                 |         |
| 84H        | 02H         | UNC_TURBO_MODE.CORE_1                 | Uncore cycles that core 1 is operating in turbo mode.                                                                                                 |         |
| 84H        | 04H         | UNC_TURBO_MODE.CORE_2                 | Uncore cycles that core 2 is operating in turbo mode.                                                                                                 |         |
| 84H        | 08H         | UNC_TURBO_MODE.CORE_3                 | Uncore cycles that core 3 is operating in turbo mode.                                                                                                 |         |
| 85H        | 02H         | UNC_CYCLES_UNHALTED_L3_FLL_ENABLE     | Uncore cycles that at least one core is unhalted and all L3 ways are enabled.                                                                         |         |
| 86H        | 01H         | UNC_CYCLES_UNHALTED_L3_FLL_DISABLE    | Uncore cycles that at least one core is unhalted and all L3 ways are disabled.                                                                        |         |

## A.5 PERFORMANCE MONITORING EVENTS FOR INTEL® XEON® PROCESSOR 5200, 5400 SERIES AND INTEL® CORE™ 2 EXTREME PROCESSORS QX 9000 SERIES

Processors based on the Enhanced Intel Core microarchitecture support the architectural and non-architectural performance-monitoring events listed in Table A-1 and Table A-10. In addition, they also support the following non-architectural performance-monitoring events listed in Table A-8. Fixed counters support the architecture events defined in Table A-9.

**Table A-8. Non-Architectural Performance Events for Processors Based on Enhanced Intel Core Microarchitecture**

| Event Num. | Umask Value | Event Mask Mnemonic                   | Description                                                                                                     | Comment |
|------------|-------------|---------------------------------------|-----------------------------------------------------------------------------------------------------------------|---------|
| COH        | 08H         | INST_RETIREDE.VM_HOST                 | Instruction retired while in VMX root operations.                                                               |         |
| D2H        | 10H         | RAT_STAALS.OTHER_SERIALIZATION_STALLS | This events counts the number of stalls due to other RAT resource serialization not counted by Umask value OFH. |         |

## A.6 PERFORMANCE MONITORING EVENTS FOR INTEL® XEON® PROCESSOR 3000, 3200, 5100, 5300 SERIES AND INTEL® CORE™ 2 DUO PROCESSORS

Processors based on the Intel Core microarchitecture support architectural and non-architectural performance-monitoring events.

Fixed-function performance counters are introduced first on processors based on Intel Core microarchitecture. Table A-9 lists pre-defined performance events that can be counted using fixed-function performance counters.

## PERFORMANCE-MONITORING EVENTS

**Table A-9. Fixed-Function Performance Counter and Pre-defined Performance Events**

| Fixed-Function Performance Counter       | Address | Event Mask Mnemonic   | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|------------------------------------------|---------|-----------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| MSR_PERF_FIXED_CTR0/IA32_PERF_FIXED_CTR0 | 309H    | Inst_Retired.Any      | This event counts the number of instructions that retire execution. For instructions that consist of multiple micro-ops, this event counts the retirement of the last micro-op of the instruction. The counter continues counting during hardware interrupts, traps, and inside interrupt handlers.                                                                                                                                                                                                                                                      |
| MSR_PERF_FIXED_CTR1/IA32_PERF_FIXED_CTR1 | 30AH    | CPU_CLK_UNHALTED.CORE | This event counts the number of core cycles while the core is not in a halt state. The core enters the halt state when it is running the HLT instruction. This event is a component in many key event ratios.<br><br>The core frequency may change from time to time due to transitions associated with Enhanced Intel SpeedStep Technology or TM2. For this reason this event may have a changing ratio with regards to time.<br><br>When the core frequency is constant, this event can approximate elapsed time while the core was not in halt state. |
| MSR_PERF_FIXED_CTR2/IA32_PERF_FIXED_CTR2 | 30BH    | CPU_CLK_UNHALTED.REF  | This event counts the number of reference cycles when the core is not in a halt state and not in a TM stop-clock state. The core enters the halt state when it is running the HLT instruction or the MWAIT instruction.                                                                                                                                                                                                                                                                                                                                  |
|                                          |         |                       | This event is not affected by core frequency changes (e.g., P states) but counts at the same frequency as the time stamp counter. This event can approximate elapsed time while the core was not in halt state and not in a TM stop-clock state.<br><br>This event has a constant ratio with the CPU_CLK_UNHALTED.BUS event.                                                                                                                                                                                                                             |

Table A-10 lists general-purpose non-architectural performance-monitoring events supported in processors based on Intel Core microarchitecture. For convenience,

Table A-10 also includes architectural events and describes minor model-specific behavior where applicable. Software must use a general-purpose performance counter to count events listed in Table A-10.

**Table A-10. Non-Architectural Performance Events in Processors Based on Intel Core Microarchitecture**

| Event Num | Umask Value | Event Name               | Definition                                                                              | Description and Comment                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|-----------|-------------|--------------------------|-----------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 03H       | 02H         | LOAD_BLOCK.STA           | Loads blocked by a preceding store with unknown address                                 | <p>This event indicates that loads are blocked by preceding stores. A load is blocked when there is a preceding store to an address that is not yet calculated. The number of events is greater or equal to the number of load operations that were blocked.</p> <p>If the load and the store are always to different addresses, check why the memory disambiguation mechanism is not working. To avoid such blocks, increase the distance between the store and the following load so that the store address is known at the time the load is dispatched.</p> |
| 03H       | 04H         | LOAD_BLOCK.STD           | Loads blocked by a preceding store with unknown data                                    | <p>This event indicates that loads are blocked by preceding stores. A load is blocked when there is a preceding store to the same address and the stored data value is not yet known. The number of events is greater or equal to the number of load operations that were blocked.</p> <p>To avoid such blocks, increase the distance between the store and the dependant load, so that the store data is known at the time the load is dispatched.</p>                                                                                                        |
| 03H       | 08H         | LOAD_BLOCK.OVERLAP_STORE | Loads that partially overlap an earlier store, or 4-Kbyte aliased with a previous store | <p>This event indicates that loads are blocked due to a variety of reasons. Some of the triggers for this event are when a load is blocked by a preceding store, in one of the following:</p> <ul style="list-style-type: none"> <li>▪ Some of the loaded byte locations are written by the preceding store and some are not.</li> <li>▪ The load is from bytes written by the preceding store, the store is aligned to its size and either:</li> </ul>                                                                                                        |

## PERFORMANCE-MONITORING EVENTS

**Table A-10. Non-Architectural Performance Events  
in Processors Based on Intel Core Microarchitecture (Contd.)**

| Event Num | Umask Value | Event Name              | Definition                     | Description and Comment                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|-----------|-------------|-------------------------|--------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|           |             |                         |                                | <ul style="list-style-type: none"> <li>▪ The load's data size is one or two bytes and it is not aligned to the store.</li> <li>▪ The load's data size is of four or eight bytes and the load is misaligned.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                  |
|           |             |                         |                                | <ul style="list-style-type: none"> <li>▪ The load is from bytes written by the preceding store, the store is misaligned and the load is not aligned on the beginning of the store.</li> <li>▪ The load is split over an eight byte boundary (excluding 16-byte loads).</li> <li>▪ The load and store have the same offset relative to the beginning of different 4-KByte pages. This case is also called 4-KByte aliasing.</li> <li>▪ In all these cases the load is blocked until after the blocking store retires and the stored data is committed to the cache hierarchy.</li> </ul> |
| 03H       | 10H         | LOAD_BLOCK_UNTIL_RETIRE | Loads blocked until retirement | <p>This event indicates that load operations were blocked until retirement. The number of events is greater or equal to the number of load operations that were blocked.</p> <p>This includes mainly uncacheable loads and split loads (loads that cross the cache line boundary) but may include other cases where loads are blocked until retirement.</p>                                                                                                                                                                                                                             |

**Table A-10. Non-Architectural Performance Events  
in Processors Based on Intel Core Microarchitecture (Contd.)**

| Event Num | Umask Value | Event Name        | Definition                                                                  | Description and Comment                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|-----------|-------------|-------------------|-----------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 03H       | 20H         | LOAD_BLOCK.L1D    | Loads blocked by the L1 data cache                                          | <p>This event indicates that loads are blocked due to one or more reasons. Some triggers for this event are:</p> <ul style="list-style-type: none"> <li>▪ The number of L1 data cache misses exceeds the maximum number of outstanding misses supported by the processor. This includes misses generated as result of demand fetches, software prefetches or hardware prefetches.</li> <li>▪ Cache line split loads.</li> <li>▪ Partial reads, such as reads to uncacheable memory, I/O instructions and more.</li> <li>▪ A locked load operation is in progress. The number of events is greater or equal to the number of load operations that were blocked.</li> </ul>     |
| 04H       | 01H         | SB_DRAIN_CYCLES   | Cycles while stores are blocked due to store buffer drain                   | <p>This event counts every cycle during which the store buffer is draining. This includes:</p> <ul style="list-style-type: none"> <li>▪ Serializing operations such as CPUID</li> <li>▪ Synchronizing operations such as XCHG</li> <li>▪ Interrupt acknowledgment</li> <li>▪ Other conditions, such as cache flushing</li> </ul>                                                                                                                                                                                                                                                                                                                                              |
| 04H       | 02H         | STORE_BLOCK.ORDER | Cycles while store is waiting for a preceding store to be globally observed | <p>This event counts the total duration, in number of cycles, which stores are waiting for a preceding stored cache line to be observed by other cores.</p> <p>This situation happens as a result of the strong store ordering behavior, as defined in "Memory Ordering," Chapter 8, <i>Intel® 64 and IA-32 Architectures Software Developer's Manual, Volume 3A</i>.</p> <p>The stall may occur and be noticeable if there are many cases when a store either misses the L1 data cache or hits a cache line in the Shared state. If the store requires a bus transaction to read the cache line then the stall ends when snoop response for the bus transaction arrives.</p> |

## PERFORMANCE-MONITORING EVENTS

**Table A-10. Non-Architectural Performance Events  
in Processors Based on Intel Core Microarchitecture (Contd.)**

| Event Num | Umask Value | Event Name        | Definition                                                               | Description and Comment                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|-----------|-------------|-------------------|--------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 04H       | 08H         | STORE_BLOCK_SNOOP | A store is blocked due to a conflict with an external or internal snoop. | This event counts the number of cycles the store port was used for snooping the L1 data cache and a store was stalled by the snoop. The store is typically resubmitted one cycle later.                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| 06H       | 00H         | SEGMENT_REG_LOADS | Number of segment register loads                                         | This event counts the number of segment register load operations. Instructions that load new values into segment registers cause a penalty.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|           |             |                   |                                                                          | <p>This event indicates performance issues in 16-bit code. If this event occurs frequently, it may be useful to calculate the number of instructions retired per segment register load. If the resulting calculation is low (on average a small number of instructions are executed between segment register loads), then the code's segment register usage should be optimized.</p> <p>As a result of branch misprediction, this event is speculative and may include segment register loads that do not actually occur. However, most segment register loads are internally serialized and such speculative effects are minimized.</p> |
| 07H       | 00H         | SSE_PRE_EXEC_NTA  | Streaming SIMD Extensions (SSE) Prefetch NTA instructions executed       | This event counts the number of times the SSE instruction prefetchNTA is executed. This instruction prefetches the data to the L1 data cache.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| 07H       | 01H         | SSE_PRE_EXEC.L1   | Streaming SIMD Extensions (SSE) PrefetchT0 instructions executed         | This event counts the number of times the SSE instruction prefetchT0 is executed. This instruction prefetches the data to the L1 data cache and L2 cache.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

**Table A-10. Non-Architectural Performance Events  
in Processors Based on Intel Core Microarchitecture (Contd.)**

| Event Num | Umask Value | Event Name             | Definition                                                                      | Description and Comment                                                                                                                                                                                                                                          |
|-----------|-------------|------------------------|---------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 07H       | 02H         | SSE_PRE_EXEC.L2        | Streaming SIMD Extensions (SSE) PrefetchT1 and PrefetchT2 instructions executed | This event counts the number of times the SSE instructions prefetchT1 and prefetchT2 are executed. These instructions prefetch the data to the L2 cache.                                                                                                         |
| 07H       | 03H         | SSE_PRE_EXEC.STORES    | Streaming SIMD Extensions (SSE) Weakly-ordered store instructions executed      | This event counts the number of times SSE non-temporal store instructions are executed.                                                                                                                                                                          |
| 08H       | 01H         | DTLB_MISSES.ANY        | Memory accesses that missed the DTLB                                            | This event counts the number of Data Table Lookaside Buffer (DTLB) misses. The count includes misses detected as a result of speculative accesses.<br>Typically a high count for this event indicates that the code accesses a large number of data pages.       |
| 08H       | 02H         | DTLB_MISSES.MISS_LD    | DTLB misses due to load operations                                              | This event counts the number of Data Table Lookaside Buffer (DTLB) misses due to load operations.<br>This count includes misses detected as a result of speculative accesses.                                                                                    |
| 08H       | 04H         | DTLB_MISSES.L0_MISS_LD | L0 DTLB misses due to load operations                                           | This event counts the number of level 0 Data Table Lookaside Buffer (DTLBO) misses due to load operations.<br>This count includes misses detected as a result of speculative accesses. Loads that miss that DTLBO and hit the DTLB1 can incur two-cycle penalty. |

## PERFORMANCE-MONITORING EVENTS

**Table A-10. Non-Architectural Performance Events  
in Processors Based on Intel Core Microarchitecture (Contd.)**

| Event Num | Umask Value | Event Name                    | Definition                                  | Description and Comment                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|-----------|-------------|-------------------------------|---------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 08H       | 08H         | DTLB_MISSES.MISS_ST           | TLB misses due to store operations          | <p>This event counts the number of Data Table Lookaside Buffer (DTLB) misses due to store operations.</p> <p>This count includes misses detected as a result of speculative accesses. Address translation for store operations is performed in the DTLB1.</p>                                                                                                                                                                                                                  |
| 09H       | 01H         | MEMORY_DISAMBIGUATION.RESET   | Memory disambiguation reset cycles          | <p>This event counts the number of cycles during which memory disambiguation misprediction occurs. As a result the execution pipeline is cleaned and execution of the mispredicted load instruction and all succeeding instructions restarts.</p> <p>This event occurs when the data address accessed by a load instruction, collides infrequently with preceding stores, but usually there is no collision. It happens rarely, and may have a penalty of about 20 cycles.</p> |
| 09H       | 02H         | MEMORY_DISAMBIGUATION.SUCCESS | Number of loads successfully disambiguated. | <p>This event counts the number of load operations that were successfully disambiguated. Loads are preceded by a store with an unknown address, but they are not blocked.</p>                                                                                                                                                                                                                                                                                                  |
| 0CH       | 01H         | PAGE_WALKS.COUNT              | Number of page-walks executed               | <p>This event counts the number of page-walks executed due to either a DTLB or ITLB miss.</p> <p>The page walk duration, PAGE_WALKS.CYCLES, divided by number of page walks is the average duration of a page walk. The average can hint whether most of the page-walks are satisfied by the caches or cause an L2 cache miss.</p>                                                                                                                                             |

**Table A-10. Non-Architectural Performance Events  
in Processors Based on Intel Core Microarchitecture (Contd.)**

| Event Num | Umask Value | Event Name        | Definition                                      | Description and Comment                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|-----------|-------------|-------------------|-------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0CH       | 02H         | PAGE_WALKS.CYCLES | Duration of page-walks in core cycles           | This event counts the duration of page-walks in core cycles. The paging mode in use typically affects the duration of page walks.<br><br>Page walk duration divided by number of page walks is the average duration of page-walks. The average can hint at whether most of the page-walks are satisfied by the caches or cause an L2 cache miss.                                                                                                                                                                                                                                                     |
| 10H       | 00H         | FP_COMP_OPS_EXE   | Floating point computational micro-ops executed | This event counts the number of floating point computational micro-ops executed. Use IA32_PMC0 only.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| 11H       | 00H         | FP_ASSIST         | Floating point assists                          | This event counts the number of floating point operations executed that required micro-code assist intervention. Assists are required in the following cases: <ul style="list-style-type: none"> <li>▪ Streaming SIMD Extensions (SSE) instructions:</li> <li>▪ Denormal input when the DAZ (Denormals Are Zeros) flag is off</li> <li>▪ Underflow result when the FTZ (Flush To Zero) flag is off</li> <li>▪ X87 instructions:</li> <li>▪ NaN or denormal are loaded to a register or used as input from memory</li> <li>▪ Division by 0</li> <li>▪ Underflow output</li> </ul> Use IA32_PMC1 only. |
| 12H       | 00H         | MUL               | Multiply operations executed                    | This event counts the number of multiply operations executed. This includes integer as well as floating point multiply operations.<br><br>Use IA32_PMC1 only.                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| 13H       | 00H         | DIV               | Divide operations executed                      | This event counts the number of divide operations executed. This includes integer divides, floating point divides and square-root operations executed.<br><br>Use IA32_PMC1 only.                                                                                                                                                                                                                                                                                                                                                                                                                    |

## PERFORMANCE-MONITORING EVENTS

**Table A-10. Non-Architectural Performance Events  
in Processors Based on Intel Core Microarchitecture (Contd.)**

| Event Num | Umask Value | Event Name          | Definition                                                         | Description and Comment                                                                                                                                                                                                                                                                                                                         |
|-----------|-------------|---------------------|--------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 14H       | 00H         | CYCLES_DIV_BUSY     | Cycles the divider busy                                            | This event counts the number of cycles the divider is busy executing divide or square root operations. The divide can be integer, X87 or Streaming SIMD Extensions (SSE). The square root operation can be either X87 or SSE. Use IA32_PMC0 only.                                                                                               |
| 18H       | 00H         | IDLE_DURING_DIV     | Cycles the divider is busy and all other execution units are idle. | This event counts the number of cycles the divider is busy (with a divide or a square root operation) and no other execution unit or load operation is in progress.<br><br>Load operations are assumed to hit the L1 data cache. This event considers only micro-ops dispatched after the divider started operating.<br><br>Use IA32_PMC0 only. |
| 19H       | 00H         | DELAYED_BYPASS.FP   | Delayed bypass to FP operation                                     | This event counts the number of times floating point operations use data immediately after the data was generated by a non-floating point execution unit. Such cases result in one penalty cycle due to data bypass between the units.<br><br>Use IA32_PMC1 only.                                                                               |
| 19H       | 01H         | DELAYED_BYPASS.SIMD | Delayed bypass to SIMD operation                                   | This event counts the number of times SIMD operations use data immediately after the data was generated by a non-SIMD execution unit. Such cases result in one penalty cycle due to data bypass between the units.<br><br>Use IA32_PMC1 only.                                                                                                   |

**Table A-10. Non-Architectural Performance Events  
in Processors Based on Intel Core Microarchitecture (Contd.)**

| Event Num | Umask Value                                  | Event Name                   | Definition                               | Description and Comment                                                                                                                                                                                                                                                                                                                                                                                                                   |
|-----------|----------------------------------------------|------------------------------|------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 19H       | 02H                                          | DELAYED_BYPASS.LOAD          | Delayed bypass to load operation         | <p>This event counts the number of delayed bypass penalty cycles that a load operation incurred.</p> <p>When load operations use data immediately after the data was generated by an integer execution unit, they may (pending on certain dynamic internal conditions) incur one penalty cycle due to delayed data bypass between the units.</p> <p>Use IA32_PMC1 only.</p>                                                               |
| 21H       | See Table 30-2                               | L2_ADS.(Core)                | Cycles L2 address bus is in use          | <p>This event counts the number of cycles the L2 address bus is being used for accesses to the L2 cache or bus queue. It can count occurrences for this core or both cores.</p>                                                                                                                                                                                                                                                           |
| 23H       | See Table 30-2                               | L2_DBUS_BUSY_RD.(Core)       | Cycles the L2 transfers data to the core | <p>This event counts the number of cycles during which the L2 data bus is busy transferring data from the L2 cache to the core. It counts for all L1 cache misses (data and instruction) that hit the L2 cache.</p> <p>This event can count occurrences for this core or both cores.</p>                                                                                                                                                  |
| 24H       | Combined mask from Table 30-2 and Table 30-4 | L2_LINES_IN.(Core, Prefetch) | L2 cache misses                          | <p>This event counts the number of cache lines allocated in the L2 cache. Cache lines are allocated in the L2 cache as a result of requests from the L1 data and instruction caches and the L2 hardware prefetchers to cache lines that are missing in the L2 cache.</p> <p>This event can count occurrences for this core or both cores. It can also count demand requests and L2 hardware prefetch requests together or separately.</p> |
| 25H       | See Table 30-2                               | L2_M_LINES_IN.(Core)         | L2 cache line modifications              | <p>This event counts whenever a modified cache line is written back from the L1 data cache to the L2 cache.</p> <p>This event can count occurrences for this core or both cores.</p>                                                                                                                                                                                                                                                      |

## PERFORMANCE-MONITORING EVENTS

**Table A-10. Non-Architectural Performance Events  
in Processors Based on Intel Core Microarchitecture (Contd.)**

| Event Num | Umask Value                                               | Event Name                               | Definition                               | Description and Comment                                                                                                                                                                                                                                                                                                                                                             |
|-----------|-----------------------------------------------------------|------------------------------------------|------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 26H       | See Table 30-2 and Table 30-4                             | L2_LINES_OUT.(Core, Prefetch)            | L2 cache lines evicted                   | <p>This event counts the number of L2 cache lines evicted.</p> <p>This event can count occurrences for this core or both cores. It can also count evictions due to demand requests and L2 hardware prefetch requests together or separately.</p>                                                                                                                                    |
| 27H       | See Table 30-2 and Table 30-4                             | L2_M_LINES_OUT.(Core, Prefetch)          | Modified lines evicted from the L2 cache | <p>This event counts the number of L2 modified cache lines evicted. These lines are written back to memory unless they also exist in a modified-state in one of the L1 data caches.</p> <p>This event can count occurrences for this core or both cores. It can also count evictions due to demand requests and L2 hardware prefetch requests together or separately.</p>           |
| 28H       | Combined mask from Table 30-2 and Table 30-5              | L2_IFETCH.(Core, Cache Line State)       | L2 cacheable instruction fetch requests  | <p>This event counts the number of instruction cache line requests from the IFU. It does not include fetch requests from uncacheable memory. It does not include ITLB miss accesses.</p> <p>This event can count occurrences for this core or both cores. It can also count accesses to cache lines at different MESI states.</p>                                                   |
| 29H       | Combined mask from Table 30-2, Table 30-4, and Table 30-5 | L2_LD.(Core, Prefetch, Cache Line State) | L2 cache reads                           | <p>This event counts L2 cache read requests coming from the L1 data cache and L2 prefetchers.</p> <p>The event can count occurrences:</p> <ul style="list-style-type: none"> <li>▪ for this core or both cores</li> <li>▪ due to demand requests and L2 hardware prefetch requests together or separately</li> <li>▪ of accesses to cache lines at different MESI states</li> </ul> |

**Table A-10. Non-Architectural Performance Events  
in Processors Based on Intel Core Microarchitecture (Contd.)**

| Event Num | Umask Value                                | Event Name                                  | Definition                                                 | Description and Comment                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|-----------|--------------------------------------------|---------------------------------------------|------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 2AH       | See Table 30-2 and Table 30-5              | L2_ST.(Core, Cache Line State)              | L2 store requests                                          | <p>This event counts all store operations that miss the L1 data cache and request the data from the L2 cache.</p> <p>The event can count occurrences for this core or both cores. It can also count accesses to cache lines at different MESI states.</p>                                                                                                                                                                                                                                             |
| 2BH       | See Table 30-2 and Table 30-5              | L2_LOCK.(Core, Cache Line State)            | L2 locked accesses                                         | <p>This event counts all locked accesses to cache lines that miss the L1 data cache.</p> <p>The event can count occurrences for this core or both cores. It can also count accesses to cache lines at different MESI states.</p>                                                                                                                                                                                                                                                                      |
| 2EH       | See Table 30-2, Table 30-4, and Table 30-5 | L2_RQSTS.(Core, Prefetch, Cache Line State) | L2 cache requests                                          | <p>This event counts all completed L2 cache requests. This includes L1 data cache reads, writes, and locked accesses, L1 data prefetch requests, instruction fetches, and all L2 hardware prefetch requests.</p> <p>This event can count occurrences:</p> <ul style="list-style-type: none"> <li>▪ for this core or both cores.</li> <li>▪ due to demand requests and L2 hardware prefetch requests together, or separately</li> <li>▪ of accesses to cache lines at different MESI states</li> </ul> |
| 2EH       | 41H                                        | L2_RQSTS.SELF_DEMAND.I_STATE                | L2 cache demand requests from this core that missed the L2 | <p>This event counts all completed L2 cache demand requests from this core that miss the L2 cache. This includes L1 data cache reads, writes, and locked accesses, L1 data prefetch requests, and instruction fetches.</p> <p>This is an architectural performance event.</p>                                                                                                                                                                                                                         |
| 2EH       | 4FH                                        | L2_RQSTS.SELF_DEMAND.MESI                   | L2 cache demand requests from this core                    | <p>This event counts all completed L2 cache demand requests from this core. This includes L1 data cache reads, writes, and locked accesses, L1 data prefetch requests, and instruction fetches.</p> <p>This is an architectural performance event.</p>                                                                                                                                                                                                                                                |

## PERFORMANCE-MONITORING EVENTS

**Table A-10. Non-Architectural Performance Events  
in Processors Based on Intel Core Microarchitecture (Contd.)**

| Event Num | Umask Value                                | Event Name                                        | Definition                                                       | Description and Comment                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|-----------|--------------------------------------------|---------------------------------------------------|------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 30H       | See Table 30-2, Table 30-4, and Table 30-5 | L2_REJECT_BUSQ.(Core, Prefetch, Cache Line State) | Rejected L2 cache requests                                       | <p>This event indicates that a pending L2 cache request that requires a bus transaction is delayed from moving to the bus queue. Some of the reasons for this event are:</p> <ul style="list-style-type: none"> <li>▪ The bus queue is full.</li> <li>▪ The bus queue already holds an entry for a cache line in the same set.</li> </ul> <p>The number of events is greater or equal to the number of requests that were rejected.</p> <ul style="list-style-type: none"> <li>▪ for this core or both cores.</li> <li>▪ due to demand requests and L2 hardware prefetch requests together, or separately.</li> <li>▪ of accesses to cache lines at different MESI states.</li> </ul> |
| 32H       | See Table 30-2                             | L2_NO_REQ.(Core)                                  | Cycles no L2 cache requests are pending                          | <p>This event counts the number of cycles that no L2 cache requests were pending from a core. When using the BOTH_CORE modifier, the event counts only if none of the cores have a pending request. The event counts also when one core is halted and the other is not halted.</p> <p>The event can count occurrences for this core or both cores.</p>                                                                                                                                                                                                                                                                                                                                |
| 3AH       | 00H                                        | EIST_TRANS                                        | Number of Enhanced Intel SpeedStep Technology (EIST) transitions | <p>This event counts the number of transitions that include a frequency change, either with or without voltage change. This includes Enhanced Intel SpeedStep Technology (EIST) and TM2 transitions.</p> <p>The event is incremented only while the counting core is in C0 state. Since transitions to higher-numbered Cx E states and TM2 transitions include a frequency change or voltage transition, the event is incremented accordingly.</p>                                                                                                                                                                                                                                    |

**Table A-10. Non-Architectural Performance Events  
in Processors Based on Intel Core Microarchitecture (Contd.)**

| Event Num | Umask Value | Event Name              | Definition                          | Description and Comment                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|-----------|-------------|-------------------------|-------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 3BH       | COH         | THERMAL_TRIP            | Number of thermal trips             | <p>This event counts the number of thermal trips. A thermal trip occurs whenever the processor temperature exceeds the thermal trip threshold temperature.</p> <p>Following a thermal trip, the processor automatically reduces frequency and voltage. The processor checks the temperature every millisecond and returns to normal when the temperature falls below the thermal trip threshold temperature.</p>                                                                                                                                                                                |
| 3CH       | OOH         | CPU_CLK_UNHALTED.CORE_P | Core cycles when core is not halted | <p>This event counts the number of core cycles while the core is not in a halt state. The core enters the halt state when it is running the HLT instruction. This event is a component in many key event ratios.</p> <p>The core frequency may change due to transitions associated with Enhanced Intel SpeedStep Technology or TM2. For this reason, this event may have a changing ratio in regard to time.</p> <p>When the core frequency is constant, this event can give approximate elapsed time while the core not in halt state.</p> <p>This is an architectural performance event.</p> |
| 3CH       | 01H         | CPU_CLK_UNHALTED.BUS    | Bus cycles when core is not halted  | <p>This event counts the number of bus cycles while the core is not in the halt state. This event can give a measurement of the elapsed time while the core was not in the halt state. The core enters the halt state when it is running the HLT instruction.</p> <p>The event also has a constant ratio with CPU_CLK_UNHALTED.REF event, which is the maximum bus to processor frequency ratio.</p> <p>Non-halted bus cycles are a component in many key event ratios.</p>                                                                                                                     |

## PERFORMANCE-MONITORING EVENTS

**Table A-10. Non-Architectural Performance Events  
in Processors Based on Intel Core Microarchitecture (Contd.)**

| Event Num | Umask Value    | Event Name                        | Definition                                             | Description and Comment                                                                                                                                                                                                                                                                                                                                                   |
|-----------|----------------|-----------------------------------|--------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 3CH       | 02H            | CPU_CLK_UNHALTED.NO_OTHER         | Bus cycles when core is active and the other is halted | <p>This event counts the number of bus cycles during which the core remains non-halted and the other core on the processor is halted.</p> <p>This event can be used to determine the amount of parallelism exploited by an application or a system. Divide this event count by the bus frequency to determine the amount of time that only one core was in use.</p>       |
| 40H       | See Table 30-5 | L1D_CACHE_LD. (Cache Line State)  | L1 cacheable data reads                                | This event counts the number of data reads from cacheable memory. Locked reads are not counted.                                                                                                                                                                                                                                                                           |
| 41H       | See Table 30-5 | L1D_CACHE_ST. (Cache Line State)  | L1 cacheable data writes                               | This event counts the number of data writes to cacheable memory. Locked writes are not counted.                                                                                                                                                                                                                                                                           |
| 42H       | See Table 30-5 | L1D_CACHE_LOCK.(Cache Line State) | L1 data cacheable locked reads                         | This event counts the number of locked data reads from cacheable memory.                                                                                                                                                                                                                                                                                                  |
| 42H       | 10H            | L1D_CACHE_LOCK_DURATION           | Duration of L1 data cacheable locked operation         | <p>This event counts the number of cycles during which any cache line is locked by any locking instruction.</p> <p>Locking happens at retirement and therefore the event does not occur for instructions that are speculatively executed. Locking duration is shorter than locked instruction execution duration.</p>                                                     |
| 43H       | 01H            | L1D_ALL_REF                       | All references to the L1 data cache                    | <p>This event counts all references to the L1 data cache, including all loads and stores with any memory types.</p> <p>The event counts memory accesses only when they are actually performed. For example, a load blocked by unknown store address and later performed is only counted once.</p> <p>The event includes non-cacheable accesses, such as I/O accesses.</p> |

**Table A-10. Non-Architectural Performance Events  
in Processors Based on Intel Core Microarchitecture (Contd.)**

| Event Num | Umask Value | Event Name        | Definition                                                    | Description and Comment                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|-----------|-------------|-------------------|---------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 43H       | 02H         | L1D_ALL_CACHE_REF | L1 Data cacheable reads and writes                            | <p>This event counts the number of data reads and writes from cacheable memory, including locked operations.</p> <p>This event is a sum of:</p> <ul style="list-style-type: none"> <li>▪ L1D_CACHE_LD.MESI</li> <li>▪ L1D_CACHE_ST.MESI</li> <li>▪ L1D_CACHE_LOCK.MESI</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                     |
| 45H       | 0FH         | L1D_REPL          | Cache lines allocated in the L1 data cache                    | This event counts the number of lines brought into the L1 data cache.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| 46H       | 00H         | L1D_M_REPL        | Modified cache lines allocated in the L1 data cache           | This event counts the number of modified lines brought into the L1 data cache.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| 47H       | 00H         | L1D_M_EVICT       | Modified cache lines evicted from the L1 data cache           | This event counts the number of modified lines evicted from the L1 data cache, whether due to replacement or by snoop HTM intervention.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| 48H       | 00H         | L1D_PEND_MISS     | Total number of outstanding L1 data cache misses at any cycle | <p>This event counts the number of outstanding L1 data cache misses at any cycle. An L1 data cache miss is outstanding from the cycle on which the miss is determined until the first chunk of data is available. This event counts:</p> <ul style="list-style-type: none"> <li>▪ all cacheable demand requests</li> <li>▪ L1 data cache hardware prefetch requests</li> <li>▪ requests to write through memory</li> <li>▪ requests to write combine memory</li> </ul> <p>Uncacheable requests are not counted. The count of this event divided by the number of L1 data cache misses, L1D_REPL, is the average duration in core cycles of an L1 data cache miss.</p> |
| 49H       | 01H         | L1D_SPLIT.LLOADS  | Cache line split loads from the L1 data cache                 | This event counts the number of load operations that span two cache lines. Such load operations are also called split loads. Split load operations are executed at retirement.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

## PERFORMANCE-MONITORING EVENTS

**Table A-10. Non-Architectural Performance Events  
in Processors Based on Intel Core Microarchitecture (Contd.)**

| Event Num | Umask Value | Event Name            | Definition                                                                                      | Description and Comment                                                                                                                                                                                                                                                     |
|-----------|-------------|-----------------------|-------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 49H       | 02H         | L1D_SPLIT_STORES      | Cache line split stores to the L1 data cache                                                    | This event counts the number of store operations that span two cache lines.                                                                                                                                                                                                 |
| 4BH       | 00H         | SSE_PRE_MISS.NTA      | Streaming SIMD Extensions (SSE) Prefetch NTA instructions missing all cache levels              | This event counts the number of times the SSE instructions prefetchNTA were executed and missed all cache levels.<br>Due to speculation an executed instruction might not retire. This instruction prefetches the data to the L1 data cache.                                |
| 4BH       | 01H         | SSE_PRE_MISS.L1       | Streaming SIMD Extensions (SSE) PrefetchT0 instructions missing all cache levels                | This event counts the number of times the SSE instructions prefetchT0 were executed and missed all cache levels.<br>Due to speculation executed instruction might not retire. The prefetchT0 instruction prefetches data to the L2 cache and L1 data cache.                 |
| 4BH       | 02H         | SSE_PRE_MISS.L2       | Streaming SIMD Extensions (SSE) PrefetchT1 and PrefetchT2 instructions missing all cache levels | This event counts the number of times the SSE instructions prefetchT1 and prefetchT2 were executed and missed all cache levels.<br>Due to speculation, an executed instruction might not retire. The prefetchT1 and PrefetchNT2 instructions prefetch data to the L2 cache. |
| 4CH       | 00H         | LOAD_HIT_PRE          | Load operations conflicting with a software prefetch to the same address                        | This event counts load operations sent to the L1 data cache while a previous Streaming SIMD Extensions (SSE) prefetch instruction to the same cache line has started prefetching but has not yet finished.                                                                  |
| 4EH       | 10H         | L1D_PREFETCH.REQUESTS | L1 data cache prefetch requests                                                                 | This event counts the number of times the L1 data cache requested to prefetch a data cache line. Requests can be rejected when the L2 cache is busy and resubmitted later or lost.<br>All requests are counted, including those that are rejected.                          |

**Table A-10. Non-Architectural Performance Events  
in Processors Based on Intel Core Microarchitecture (Contd.)**

| Event Num | Umask Value                   | Event Name                                     | Definition                                            | Description and Comment                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|-----------|-------------------------------|------------------------------------------------|-------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 60H       | See Table 30-2 and Table 30-3 | BUS_REQUEST_OUTSTANDING. (Core and Bus Agents) | Outstanding cacheable data read bus requests duration | <p>This event counts the number of pending full cache line read transactions on the bus occurring in each cycle. A read transaction is pending from the cycle it is sent on the bus until the full cache line is received by the processor.</p> <p>The event counts only full-line cacheable read requests from either the L1 data cache or the L2 prefetchers. It does not count Read for Ownership transactions, instruction byte fetch transactions, or any other bus transaction.</p>                                                                                                      |
| 61H       | See Table 30-3.               | BUS_BNR_DRV. (Bus Agents)                      | Number of Bus Not Ready signals asserted              | <p>This event counts the number of Bus Not Ready (BNR) signals that the processor asserts on the bus to suspend additional bus requests by other bus agents.</p> <p>A bus agent asserts the BNR signal when the number of data and snoop transactions is close to the maximum that the bus can handle. To obtain the number of bus cycles during which the BNR signal is asserted, multiply the event count by two.</p> <p>While this signal is asserted, new transactions cannot be submitted on the bus. As a result, transaction latency may have higher impact on program performance.</p> |

## PERFORMANCE-MONITORING EVENTS

**Table A-10. Non-Architectural Performance Events  
in Processors Based on Intel Core Microarchitecture (Contd.)**

| Event Num | Umask Value                   | Event Name                            | Definition                               | Description and Comment                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|-----------|-------------------------------|---------------------------------------|------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 62H       | See Table 30-3                | BUS_DRDY_CLOCKS.(Bus Agents)          | Bus cycles when data is sent on the bus  | <p>This event counts the number of bus cycles during which the DRDY (Data Ready) signal is asserted on the bus. The DRDY signal is asserted when data is sent on the bus. With the 'THIS_AGENT' mask this event counts the number of bus cycles during which this agent (the processor) writes data on the bus back to memory or to other bus agents. This includes all explicit and implicit data writebacks, as well as partial writes.</p> <p>With the 'ALL_AGENTS' mask, this event counts the number of bus cycles during which any bus agent sends data on the bus. This includes all data reads and writes on the bus.</p> |
| 63H       | See Table 30-2 and Table 30-3 | BUS_LOCK_CLOCKS.(Core and Bus Agents) | Bus cycles when a LOCK signal asserted   | <p>This event counts the number of bus cycles, during which the LOCK signal is asserted on the bus. A LOCK signal is asserted when there is a locked memory access, due to:</p> <ul style="list-style-type: none"> <li>▪ uncacheable memory</li> <li>▪ locked operation that spans two cache lines</li> <li>▪ page-walk from an uncacheable page table</li> </ul> <p>Bus locks have a very high performance penalty and it is highly recommended to avoid such accesses.</p>                                                                                                                                                      |
| 64H       | See Table 30-2                | BUS_DATA_RCV.(Core)                   | Bus cycles while processor receives data | This event counts the number of bus cycles during which the processor is busy receiving data.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| 65H       | See Table 30-2 and Table 30-3 | BUS_TRANS_BRD.(Core and Bus Agents)   | Burst read bus transactions              | <p>This event counts the number of burst read transactions including:</p> <ul style="list-style-type: none"> <li>▪ L1 data cache read misses (and L1 data cache hardware prefetches)</li> <li>▪ L2 hardware prefetches by the DPL and L2 streamer</li> <li>▪ IFU read misses of cacheable lines.</li> </ul> <p>It does not include RFO transactions.</p>                                                                                                                                                                                                                                                                          |

**Table A-10. Non-Architectural Performance Events  
in Processors Based on Intel Core Microarchitecture (Contd.)**

| Event Num | Umask Value                    | Event Name                             | Definition                          | Description and Comment                                                                                                                                                                                                                                                                            |
|-----------|--------------------------------|----------------------------------------|-------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 66H       | See Table 30-2 and Table 30-3. | BUS_TRANS_RFO.(Core and Bus Agents)    | RFO bus transactions                | This event counts the number of Read For Ownership (RFO) bus transactions, due to store operations that miss the L1 data cache and the L2 cache. It also counts RFO bus transactions due to locked operations.                                                                                     |
| 67H       | See Table 30-2 and Table 30-3. | BUS_TRANS_WB.(Core and Bus Agents)     | Explicit writeback bus transactions | This event counts all explicit writeback bus transactions due to dirty line evictions. It does not count implicit writebacks due to invalidation by a snoop request.                                                                                                                               |
| 68H       | See Table 30-2 and Table 30-3  | BUS_TRANS_IFETCH.(Core and Bus Agents) | Instruction-fetch bus transactions  | This event counts all instruction fetch full cache line bus transactions.                                                                                                                                                                                                                          |
| 69H       | See Table 30-2 and Table 30-3  | BUS_TRANS_INVAL.(Core and Bus Agents)  | Invalidate bus transactions         | This event counts all invalidate transactions. Invalidate transactions are generated when: <ul style="list-style-type: none"> <li>▪ A store operation hits a shared line in the L2 cache.</li> <li>▪ A full cache line write misses the L2 cache or hits a shared line in the L2 cache.</li> </ul> |
| 6AH       | See Table 30-2 and Table 30-3  | BUS_TRANS_PWR.(Core and Bus Agents)    | Partial write bus transaction       | This event counts partial write bus transactions.                                                                                                                                                                                                                                                  |
| 6BH       | See Table 30-2 and Table 30-3  | BUS_TRANS_P.(Core and Bus Agents)      | Partial bus transactions            | This event counts all (read and write) partial bus transactions.                                                                                                                                                                                                                                   |

## PERFORMANCE-MONITORING EVENTS

**Table A-10. Non-Architectural Performance Events  
in Processors Based on Intel Core Microarchitecture (Contd.)**

| Event Num | Umask Value                   | Event Name                            | Definition                               | Description and Comment                                                                                                                                                                                                                                                                  |
|-----------|-------------------------------|---------------------------------------|------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 6CH       | See Table 30-2 and Table 30-3 | BUS_TRANS_IO.(Core and Bus Agents)    | IO bus transactions                      | This event counts the number of completed I/O bus transactions as a result of IN and OUT instructions. The count does not include memory mapped IO.                                                                                                                                      |
| 6DH       | See Table 30-2 and Table 30-3 | BUS_TRANS_DEF.(Core and Bus Agents)   | Deferred bus transactions                | This event counts the number of deferred transactions.                                                                                                                                                                                                                                   |
| 6EH       | See Table 30-2 and Table 30-3 | BUS_TRANS_BURST.(Core and Bus Agents) | Burst (full cache-line) bus transactions | This event counts burst (full cache line) transactions including: <ul style="list-style-type: none"> <li>▪ Burst reads</li> <li>▪ RFOs</li> <li>▪ Explicit writebacks</li> <li>▪ Write combine lines</li> </ul>                                                                          |
| 6FH       | See Table 30-2 and Table 30-3 | BUS_TRANS_MEM.(Core and Bus Agents)   | Memory bus transactions                  | This event counts all memory bus transactions including: <ul style="list-style-type: none"> <li>▪ Burst transactions</li> <li>▪ Partial reads and writes - invalidate transactions</li> </ul> The BUS_TRANS_MEM count is the sum of BUS_TRANS_BURST, BUS_TRANS_P and BUS_TRANS_IVAL.     |
| 70H       | See Table 30-2 and Table 30-3 | BUS_TRANS_ANY.(Core and Bus Agents)   | All bus transactions                     | This event counts all bus transactions. This includes: <ul style="list-style-type: none"> <li>▪ Memory transactions</li> <li>▪ IO transactions (non memory-mapped)</li> <li>▪ Deferred transaction completion</li> <li>▪ Other less frequent transactions, such as interrupts</li> </ul> |

**Table A-10. Non-Architectural Performance Events  
in Processors Based on Intel Core Microarchitecture (Contd.)**

| Event Num | Umask Value                   | Event Name                              | Definition                          | Description and Comment                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|-----------|-------------------------------|-----------------------------------------|-------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 77H       | See Table 30-2 and Table 30-6 | EXT_SNOOP. (Bus Agents, Snoop Response) | External snoops                     | This event counts the snoop responses to bus transactions. Responses can be counted separately by type and by bus agent.<br>With the 'THIS_AGENT' mask, the event counts snoop responses from this processor to bus transactions sent by this processor. With the 'ALL_AGENTS' mask the event counts all snoop responses seen on the bus.                                                                                                                                                                                                                                                                                                                                                               |
| 78H       | See Table 30-2 and Table 30-7 | CMP_SNOOP.(Core, Snoop Type)            | L1 data cache snooped by other core | This event counts the number of times the L1 data cache is snooped for a cache line that is needed by the other core in the same processor. The cache line is either missing in the L1 instruction or data caches of the other core, or is available for reading only and the other core wishes to write the cache line.                                                                                                                                                                                                                                                                                                                                                                                |
|           |                               |                                         |                                     | The snoop operation may change the cache line state. If the other core issued a read request that hit this core in E state, typically the state changes to S state in this core. If the other core issued a read for ownership request (due a write miss or hit to S state) that hits this core's cache line in E or S state, this typically results in invalidation of the cache line in this core. If the snoop hits a line in M state, the state is changed at a later opportunity.<br>These snoops are performed through the L1 data cache store port. Therefore, frequent snoops may conflict with extensive stores to the L1 data cache, which may increase store latency and impact performance. |
| 7AH       | See Table 30-3                | BUS_HIT_DRV. (Bus Agents)               | HIT signal asserted                 | This event counts the number of bus cycles during which the processor drives the HIT# pin to signal HIT snoop response.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

## PERFORMANCE-MONITORING EVENTS

**Table A-10. Non-Architectural Performance Events  
in Processors Based on Intel Core Microarchitecture (Contd.)**

| Event Num | Umask Value                   | Event Name                            | Definition                           | Description and Comment                                                                                                                                                                                                                                                                                                                                                                                                                |
|-----------|-------------------------------|---------------------------------------|--------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7BH       | See Table 30-3                | BUS_HITM_DRV. (Bus Agents)            | HITM signal asserted                 | This event counts the number of bus cycles during which the processor drives the HITM# pin to signal HITM snoop response.                                                                                                                                                                                                                                                                                                              |
| 7DH       | See Table 30-2                | BUSQ_EMPTY. (Core)                    | Bus queue empty                      | This event counts the number of cycles during which the core did not have any pending transactions in the bus queue. It also counts when the core is halted and the other core is not halted.<br><br>This event can count occurrences for this core or both cores.                                                                                                                                                                     |
| 7EH       | See Table 30-2 and Table 30-3 | SNOOP_STALL_DRV.(Core and Bus Agents) | Bus stalled for snoops               | This event counts the number of times that the bus snoop stall signal is asserted. To obtain the number of bus cycles during which snoops on the bus are prohibited, multiply the event count by two.<br><br>During the snoop stall cycles, no new bus transactions requiring a snoop response can be initiated on the bus. A bus agent asserts a snoop stall signal if it cannot response to a snoop request within three bus cycles. |
| 7FH       | See Table 30-2                | BUS_IO_WAIT. (Core)                   | IO requests waiting in the bus queue | This event counts the number of core cycles during which IO requests wait in the bus queue. With the SELF modifier this event counts IO requests per core.<br><br>With the BOTH_CORE modifier, this event increments by one for any cycle for which there is a request from either core.                                                                                                                                               |
| 80H       | 00H                           | L1I_READS                             | Instruction fetches                  | This event counts all instruction fetches, including uncacheable fetches that bypass the Instruction Fetch Unit (IFU).                                                                                                                                                                                                                                                                                                                 |
| 81H       | 00H                           | L1I_MISSES                            | Instruction Fetch Unit misses        | This event counts all instruction fetches that miss the Instruction Fetch Unit (IFU) or produce memory requests. This includes uncacheable fetches.<br><br>An instruction fetch miss is counted only once and not once for every cycle it is outstanding.                                                                                                                                                                              |

**Table A-10. Non-Architectural Performance Events  
in Processors Based on Intel Core Microarchitecture (Contd.)**

| Event Num | Umask Value | Event Name             | Definition                                                              | Description and Comment                                                                                                                                                                                                                                                                         |
|-----------|-------------|------------------------|-------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 82H       | 02H         | ITLB.SMALL_MISS        | ITLB small page misses                                                  | This event counts the number of instruction fetches from small pages that miss the ITLB.                                                                                                                                                                                                        |
| 82H       | 10H         | ITLB.LARGE_MISS        | ITLB large page misses                                                  | This event counts the number of instruction fetches from large pages that miss the ITLB.                                                                                                                                                                                                        |
| 82H       | 40H         | ITLB.FLUSH             | ITLB flushes                                                            | This event counts the number of ITLB flushes. This usually happens upon CR3 or CRO writes, which are executed by the operating system during process switches.                                                                                                                                  |
| 82H       | 12H         | ITLB.MISSES            | ITLB misses                                                             | This event counts the number of instruction fetches from either small or large pages that miss the ITLB.                                                                                                                                                                                        |
| 83H       | 02H         | INST_QUEUE.FULL        | Cycles during which the instruction queue is full                       | This event counts the number of cycles during which the instruction queue is full. In this situation, the core front-end stops fetching more instructions. This is an indication of very long stalls in the back-end pipeline stages.                                                           |
| 86H       | 00H         | CYCLES_L1I_MEM_STALLED | Cycles during which instruction fetches stalled                         | This event counts the number of cycles for which an instruction fetch stalls, including stalls due to any of the following reasons: <ul style="list-style-type: none"> <li>▪ instruction Fetch Unit cache misses</li> <li>▪ instruction TLB misses</li> <li>▪ instruction TLB faults</li> </ul> |
| 87H       | 00H         | ILD_STALL              | Instruction Length Decoder stall cycles due to a length changing prefix | This event counts the number of cycles during which the instruction length decoder uses the slow length decoder. Usually, instruction length decoding is done in one cycle. When the slow decoder is used, instruction decoding requires 6 cycles.                                              |

## PERFORMANCE-MONITORING EVENTS

**Table A-10. Non-Architectural Performance Events  
in Processors Based on Intel Core Microarchitecture (Contd.)**

| Event Num | Umask Value | Event Name        | Definition                                            | Description and Comment                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|-----------|-------------|-------------------|-------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|           |             |                   |                                                       | <p>The slow decoder is used in the following cases:</p> <ul style="list-style-type: none"> <li>▪ operand override prefix (66H) preceding an instruction with immediate data</li> <li>▪ address override prefix (67H) preceding an instruction with a modr/m in real, big real, 16-bit protected or 32-bit protected modes</li> </ul> <p>To avoid instruction length decoding stalls, generate code using imm8 or imm32 values instead of imm16 values. If you must use an imm16 value, store the value in a register using "mov reg, imm32" and use the register format of the instruction.</p> |
| 88H       | 00H         | BR_INST_EXEC      | Branch instructions executed                          | <p>This event counts all executed branches (not necessarily retired). This includes only instructions and not micro-op branches.</p> <p>Frequent branching is not necessarily a major performance issue. However frequent branch mispredictions may be a problem.</p>                                                                                                                                                                                                                                                                                                                           |
| 89H       | 00H         | BR_MISSP_EXEC     | Mispredicted branch instructions executed             | This event counts the number of mispredicted branch instructions that were executed.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| 8AH       | 00H         | BR_BAC_MISSP_EXEC | Branch instructions mispredicted at decoding          | This event counts the number of branch instructions that were mispredicted at decoding.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| 8BH       | 00H         | BR_CND_EXEC       | Conditional branch instructions executed.             | This event counts the number of conditional branch instructions executed, but not necessarily retired.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| 8CH       | 00H         | BR_CND_MISSP_EXEC | Mispredicted conditional branch instructions executed | This event counts the number of mispredicted conditional branch instructions that were executed.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

**Table A-10. Non-Architectural Performance Events  
in Processors Based on Intel Core Microarchitecture (Contd.)**

| Event Num | Umask Value | Event Name            | Definition                                         | Description and Comment                                                                                                                                                                                                                                                                                                                                                                                                                            |
|-----------|-------------|-----------------------|----------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 8DH       | 00H         | BR_IND_EXEC           | Indirect branch instructions executed              | This event counts the number of indirect branch instructions that were executed.                                                                                                                                                                                                                                                                                                                                                                   |
| 8EH       | 00H         | BR_IND_MISSP_EXEC     | Mispredicted indirect branch instructions executed | This event counts the number of mispredicted indirect branch instructions that were executed.                                                                                                                                                                                                                                                                                                                                                      |
| 8FH       | 00H         | BR_RET_EXEC           | RET instructions executed                          | This event counts the number of RET instructions that were executed.                                                                                                                                                                                                                                                                                                                                                                               |
| 90H       | 00H         | BR_RET_MISSP_EXEC     | Mispredicted RET instructions executed             | This event counts the number of mispredicted RET instructions that were executed.                                                                                                                                                                                                                                                                                                                                                                  |
| 91H       | 00H         | BR_RET_BAC_MISSP_EXEC | RET instructions executed mispredicted at decoding | This event counts the number of RET instructions that were executed and were mispredicted at decoding.                                                                                                                                                                                                                                                                                                                                             |
| 92H       | 00H         | BR_CALL_EXEC          | CALL instructions executed                         | This event counts the number of CALL instructions executed.                                                                                                                                                                                                                                                                                                                                                                                        |
| 93H       | 00H         | BR_CALL_MISSP_EXEC    | Mispredicted CALL instructions executed            | This event counts the number of mispredicted CALL instructions that were executed.                                                                                                                                                                                                                                                                                                                                                                 |
| 94H       | 00H         | BR_IND_CALL_EXEC      | Indirect CALL instructions executed                | This event counts the number of indirect CALL instructions that were executed.                                                                                                                                                                                                                                                                                                                                                                     |
| 97H       | 00H         | BR_TKN_BUBBLE_1       | Branch predicted taken with bubble 1               | The events BR_TKN_BUBBLE_1 and BR_TKN_BUBBLE_2 together count the number of times a taken branch prediction incurred a one-cycle penalty. The penalty incurs when: <ul style="list-style-type: none"> <li>▪ Too many taken branches are placed together. To avoid this, unroll loops and add a non-taken branch in the middle of the taken sequence.</li> <li>▪ The branch target is unaligned. To avoid this, align the branch target.</li> </ul> |

## PERFORMANCE-MONITORING EVENTS

**Table A-10. Non-Architectural Performance Events  
in Processors Based on Intel Core Microarchitecture (Contd.)**

| Event Num | Umask Value | Event Name                | Definition                                          | Description and Comment                                                                                                                                                                                                                                                                                                                                                                                                                               |
|-----------|-------------|---------------------------|-----------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 98H       | 00H         | BR_TKN_BUBBLE_2           | Branch predicted taken with bubble 2                | <p>The events BR_TKN_BUBBLE_1 and BR_TKN_BUBBLE_2 together count the number of times a taken branch prediction incurred a one-cycle penalty. The penalty incurs when:</p> <ul style="list-style-type: none"> <li>Too many taken branches are placed together. To avoid this, unroll loops and add a non-taken branch in the middle of the taken sequence.</li> <li>The branch target is unaligned. To avoid this, align the branch target.</li> </ul> |
| A0H       | 00H         | RS_UOPS_DISPATCHED        | Micro-ops dispatched for execution                  | This event counts the number of micro-ops dispatched for execution. Up to six micro-ops can be dispatched in each cycle.                                                                                                                                                                                                                                                                                                                              |
| A1H       | 01H         | RS_UOPS_DISPATCHED.PORT 0 | Cycles micro-ops dispatched for execution on port 0 | This event counts the number of cycles for which micro-ops dispatched for execution. Each cycle, at most one micro-op can be dispatched on the port. Issue Ports are described in <i>Intel® 64 and IA-32 Architectures Optimization Reference Manual</i> . Use IA32_PMC0 only.                                                                                                                                                                        |
| A1H       | 02H         | RS_UOPS_DISPATCHED.PORT 1 | Cycles micro-ops dispatched for execution on port 1 | This event counts the number of cycles for which micro-ops dispatched for execution. Each cycle, at most one micro-op can be dispatched on the port. Use IA32_PMC0 only.                                                                                                                                                                                                                                                                              |
| A1H       | 04H         | RS_UOPS_DISPATCHED.PORT 2 | Cycles micro-ops dispatched for execution on port 2 | This event counts the number of cycles for which micro-ops dispatched for execution. Each cycle, at most one micro-op can be dispatched on the port. Use IA32_PMC0 only.                                                                                                                                                                                                                                                                              |
| A1H       | 08H         | RS_UOPS_DISPATCHED.PORT 3 | Cycles micro-ops dispatched for execution on port 3 | This event counts the number of cycles for which micro-ops dispatched for execution. Each cycle, at most one micro-op can be dispatched on the port. Use IA32_PMC0 only.                                                                                                                                                                                                                                                                              |

in Processors Based on Intel Core Microarchitecture (Contd.)**

| Event Num | Umask Value | Event Name                | Definition                                          | Description and Comment                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|-----------|-------------|---------------------------|-----------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| A1H       | 10H         | RS_UOPS_DISPATCHED.PORT 4 | Cycles micro-ops dispatched for execution on port 4 | This event counts the number of cycles for which micro-ops dispatched for execution. Each cycle, at most one micro-op can be dispatched on the port. Use IA32_PMC0 only.                                                                                                                                                                                                                                                                                                              |
| A1H       | 20H         | RS_UOPS_DISPATCHED.PORT 5 | Cycles micro-ops dispatched for execution on port 5 | This event counts the number of cycles for which micro-ops dispatched for execution. Each cycle, at most one micro-op can be dispatched on the port. Use IA32_PMC0 only.                                                                                                                                                                                                                                                                                                              |
| AAH       | 01H         | MACRO_INSTS. DECODED      | Instructions decoded                                | This event counts the number of instructions decoded (but not necessarily executed or retired).                                                                                                                                                                                                                                                                                                                                                                                       |
| AAH       | 08H         | MACRO_INSTS. CISC_DECODED | CISC Instructions decoded                           | This event counts the number of complex instructions decoded. Complex instructions usually have more than four micro-ops. Only one complex instruction can be decoded at a time.                                                                                                                                                                                                                                                                                                      |
| ABH       | 01H         | ESP.SYNCH                 | ESP register content synchronization                | This event counts the number of times that the ESP register is explicitly used in the address expression of a load or store operation, after it is implicitly used, for example by a push or a pop instruction. ESP synch micro-op uses resources from the rename pipe-stage and up to retirement. The expected ratio of this event divided by the number of ESP implicit changes is 0,2. If the ratio is higher, consider rearranging your code to avoid ESP synchronization events. |

## PERFORMANCE-MONITORING EVENTS

**Table A-10. Non-Architectural Performance Events  
in Processors Based on Intel Core Microarchitecture (Contd.)**

| Event Num | Umask Value | Event Name                    | Definition                                   | Description and Comment                                                                                                                                                                                                                                                                                                                                                                                                                     |
|-----------|-------------|-------------------------------|----------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ABH       | 02H         | ESP.ADDITIONS                 | ESP register automatic additions             | <p>This event counts the number of ESP additions performed automatically by the decoder. A high count of this event is good, since each automatic addition performed by the decoder saves a micro-op from the execution units.</p> <p>To maximize the number of ESP additions performed automatically by the decoder, choose instructions that implicitly use the ESP, such as PUSH, POP, CALL, and RET instructions whenever possible.</p> |
| BOH       | 00H         | SIMD_UOPS_EXEC                | SIMD micro-ops executed (excluding stores)   | This event counts all the SIMD micro-ops executed. It does not count MOVO and MOVD stores from register to memory.                                                                                                                                                                                                                                                                                                                          |
| B1H       | 00H         | SIMD_SAT_UOP_EXEC             | SIMD saturated arithmetic micro-ops executed | This event counts the number of SIMD saturated arithmetic micro-ops executed.                                                                                                                                                                                                                                                                                                                                                               |
| B3H       | 01H         | SIMD_UOP_TYPE_EXEC.MUL        | SIMD packed multiply micro-ops executed      | This event counts the number of SIMD packed multiply micro-ops executed.                                                                                                                                                                                                                                                                                                                                                                    |
| B3H       | 02H         | SIMD_UOP_TYPE_EXEC.SHIFT      | SIMD packed shift micro-ops executed         | This event counts the number of SIMD packed shift micro-ops executed.                                                                                                                                                                                                                                                                                                                                                                       |
| B3H       | 04H         | SIMD_UOP_TYPE_EXEC.PACK       | SIMD pack micro-ops executed                 | This event counts the number of SIMD pack micro-ops executed.                                                                                                                                                                                                                                                                                                                                                                               |
| B3H       | 08H         | SIMD_UOP_TYPE_EXEC.UNPACK     | SIMD unpack micro-ops executed               | This event counts the number of SIMD unpack micro-ops executed.                                                                                                                                                                                                                                                                                                                                                                             |
| B3H       | 10H         | SIMD_UOP_TYPE_EXEC.LOGICAL    | SIMD packed logical micro-ops executed       | This event counts the number of SIMD packed logical micro-ops executed.                                                                                                                                                                                                                                                                                                                                                                     |
| B3H       | 20H         | SIMD_UOP_TYPE_EXEC.ARITHMETIC | SIMD packed arithmetic micro-ops executed    | This event counts the number of SIMD packed arithmetic micro-ops executed.                                                                                                                                                                                                                                                                                                                                                                  |

| COH       | 00H         | INST_RETIRED.<br>ANY_P   | Instructions retired                                            | This event counts the number of instructions that retire execution. For instructions that consist of multiple micro-ops, this event counts the retirement of the last micro-op of the instruction. The counter continues counting during hardware interrupts, traps, and inside interrupt handlers.<br>INST_RETIRED.ANY_P is an architectural performance event. |
| COH       | 01H         | INST_RETIRED.<br>LOADS   | Instructions retired, which contain a load                      | This event counts the number of instructions retired that contain a load operation.                                                                                                                                                                                                                                                                              |
| COH       | 02H         | INST_RETIRED.<br>STORES  | Instructions retired, which contain a store                     | This event counts the number of instructions retired that contain a store operation.                                                                                                                                                                                                                                                                             |
| COH       | 04H         | INST_RETIRED.<br>OTHER   | Instructions retired, with no load or store operation           | This event counts the number of instructions retired that do not contain a load or a store operation.                                                                                                                                                                                                                                                            |
| C1H       | 01H         | X87_OPS_<br>RETIRED.FXCH | FXCH instructions retired                                       | This event counts the number of FXCH instructions retired. Modern compilers generate more efficient code and are less likely to use this instruction. If you obtain a high count for this event consider recompiling the code.                                                                                                                                   |
| C1H       | FEH         | X87_OPS_<br>RETIRED.ANY  | Retired floating-point computational operations (precise event) | This event counts the number of floating-point computational operations retired. It counts: <ul style="list-style-type: none"> <li>▪ floating point computational operations executed by the assist handler</li> <li>▪ sub-operations of complex floating-point instructions like transcendental instructions</li> </ul>                                         |

## PERFORMANCE-MONITORING EVENTS

**Table A-10. Non-Architectural Performance Events  
in Processors Based on Intel Core Microarchitecture (Contd.)**

| Event Num | Umask Value | Event Name                 | Definition                                          | Description and Comment                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|-----------|-------------|----------------------------|-----------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|           |             |                            |                                                     | <p>This event does not count:</p> <ul style="list-style-type: none"> <li>▪ floating-point computational operations that cause traps or assists.</li> <li>▪ floating-point loads and stores.</li> </ul> <p>When this event is captured with the precise event mechanism, the collected samples contain the address of the instruction that was executed immediately after the instruction that caused the event.</p>                                                                                                                                                                                                                                                                                                                                                                                                    |
| C2H       | 01H         | UOPS_RETIRED.<br>LD_IND_BR | Fused load+op<br>or load+indirect<br>branch retired | <p>This event counts the number of retired micro-ops that fused a load with another operation. This includes:</p> <ul style="list-style-type: none"> <li>▪ Fusion of a load and an arithmetic operation, such as with the following instruction: ADD EAX, [EBX] where the content of the memory location specified by EBX register is loaded, added to EXA register, and the result is stored in EAX.</li> <li>▪ Fusion of a load and a branch in an indirect branch operation, such as with the following instructions:           <ul style="list-style-type: none"> <li>▪ JMP [RDI+200]</li> <li>▪ RET</li> </ul> </li> <li>▪ Fusion decreases the number of micro-ops in the processor pipeline. A high value for this event count indicates that the code is using the processor resources effectively.</li> </ul> |
| C2H       | 02H         | UOPS_RETIRED.<br>STD_STA   | Fused store<br>address + data<br>retired            | <p>This event counts the number of store address calculations that are fused with store data emission into one micro-op. Traditionally, each store operation required two micro-ops.</p> <p>This event counts fusion of retired micro-ops only. Fusion decreases the number of micro-ops in the processor pipeline. A high value for this event count indicates that the code is using the processor resources effectively.</p>                                                                                                                                                                                                                                                                                                                                                                                        |

**Table A-10. Non-Architectural Performance Events  
in Processors Based on Intel Core Microarchitecture (Contd.)**

| Event Num | Umask Value | Event Name                | Definition                                        | Description and Comment                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

|           |             |                                |                                                                                                   | <p>Some instructions are decoded into longer sequences such as repeat instructions, floating point transcendental instructions, and assists. In some cases micro-op sequences are fused or whole instructions are fused into one micro-op.</p> <p>See other UOPS_RETired events for differentiating retired fused and non-fused micro-ops.</p>                                                                                                                                                                                                                                                                                                                                             |
| C3H       | 01H         | MACHINE_NUKES.SMC              | Self-Modifying Code detected                                                                      | <p>This event counts the number of times that a program writes to a code section. Self-modifying code causes a severe penalty in all Intel 64 and IA-32 processors.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| C3H       | 04H         | MACHINE_NUKES.MEM_ORDER        | Execution pipeline restart due to memory ordering conflict or memory disambiguation misprediction | <p>This event counts the number of times the pipeline is restarted due to either multi-threaded memory ordering conflicts or memory disambiguation misprediction.</p> <p>A multi-threaded memory ordering conflict occurs when a store, which is executed in another core, hits a load that is executed out of order in this core but not yet retired. As a result, the load needs to be restarted to satisfy the memory ordering model.</p> <p>See Chapter 8, "Multiple-Processor Management" in the <i>Intel® 64 and IA-32 Architectures Software Developer's Manual, Volume 3A</i>.</p> <p>To count memory disambiguation mispredictions, use the event MEMORY_DISAMBIGATION.RESET.</p> |
| C4H       | 00H         | BR_INST_RETired.ANY            | Retired branch instructions                                                                       | <p>This event counts the number of branch instructions retired. This is an architectural performance event.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| C4H       | 01H         | BR_INST_RETired.PRED_NOT_TAKEN | Retired branch instructions that were predicted not-taken                                         | <p>This event counts the number of branch instructions retired that were correctly predicted to be not-taken.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

**Table A-10. Non-Architectural Performance Events  
in Processors Based on Intel Core Microarchitecture (Contd.)**

| Event Num | Umask Value | Event Name                        | Definition                                                   | Description and Comment                                                                                                                                                                                                                                                     |
|-----------|-------------|-----------------------------------|--------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| C4H       | 02H         | BR_INST_RETIRED.MISPRED_NOT_TAKEN | Retired branch instructions that were mispredicted not-taken | This event counts the number of branch instructions retired that were mispredicted and not-taken.                                                                                                                                                                           |
| C4H       | 04H         | BR_INST_RETIRED.PRED_TAKEN        | Retired branch instructions that were predicted taken        | This event counts the number of branch instructions retired that were correctly predicted to be taken.                                                                                                                                                                      |
| C4H       | 08H         | BR_INST_RETIRED.MISPRED_TAKEN     | Retired branch instructions that were mispredicted taken     | This event counts the number of branch instructions retired that were mispredicted and taken.                                                                                                                                                                               |
| C4H       | 0CH         | BR_INST_RETIRED.TAKEN             | Retired taken branch instructions                            | This event counts the number of branches retired that were taken.                                                                                                                                                                                                           |
| C5H       | 00H         | BR_INST_RETIRED.MISPRED           | Retired mispredicted branch instructions. (precise event)    | This event counts the number of retired branch instructions that were mispredicted by the processor. A branch misprediction occurs when the processor predicts that the branch would be taken, but it is not, or vice-versa.<br>This is an architectural performance event. |
| C6H       | 01H         | CYCLES_INT_MASKED                 | Cycles during which interrupts are disabled                  | This event counts the number of cycles during which interrupts are disabled.                                                                                                                                                                                                |
| C6H       | 02H         | CYCLES_INT_PENDING_AND_MASKED     | Cycles during which interrupts are pending and disabled      | This event counts the number of cycles during which there are pending interrupts but interrupts are disabled.                                                                                                                                                               |
| C7H       | 01H         | SIMD_INST_RETIRED.PACKED_SINGLE   | Retired SSE packed-single instructions                       | This event counts the number of SSE packed-single instructions retired.                                                                                                                                                                                                     |
| C7H       | 02H         | SIMD_INST_RETIRED.SCALAR_SINGLE   | Retired SSE scalar-single instructions                       | This event counts the number of SSE scalar-single instructions retired.                                                                                                                                                                                                     |

## PERFORMANCE-MONITORING EVENTS

**Table A-10. Non-Architectural Performance Events  
in Processors Based on Intel Core Microarchitecture (Contd.)**

| Event Num | Umask Value | Event Name                      | Definition                                          | Description and Comment                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

**Table A-10. Non-Architectural Performance Events  
in Processors Based on Intel Core Microarchitecture (Contd.)**

| Event Num | Umask Value | Event Name                 | Definition                                                       | Description and Comment                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|-----------|-------------|----------------------------|------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| CBH       | 10H         | MEM_LOAD_RETired.DTLB_MISS | Retired loads that miss the DTLB (precise event)                 | <p>This event counts the number of retired loads that missed the DTLB. The DTLB miss is not counted if the load operation causes a fault.</p> <p>This event counts loads from cacheable memory only. The event does not count loads by software prefetches.</p> <p>When this event is captured with the precise event mechanism, the collected samples contain the address of the instruction that was executed immediately after the instruction that caused the event.</p> <p>Use IA32_PMC0 only.</p> |
| CCH       | 01H         | FP_MMX_TRANS_TO_MMX        | Transitions from Floating Point to MMX Instructions              | This event counts the first MMX instructions following a floating-point instruction. Use this event to estimate the penalties for the transitions between floating-point and MMX states.                                                                                                                                                                                                                                                                                                                |
| CCH       | 02H         | FP_MMX_TRANS_TO_FP         | Transitions from MMX Instructions to Floating Point Instructions | This event counts the first floating-point instructions following any MMX instruction. Use this event to estimate the penalties for the transitions between floating-point and MMX states.                                                                                                                                                                                                                                                                                                              |
| CDH       | 00H         | SIMD_ASSIST                | SIMD assists invoked                                             | This event counts the number of SIMD assists invoked. SIMD assists are invoked when an EMMS instruction is executed, changing the MMX state in the floating point stack.                                                                                                                                                                                                                                                                                                                                |
| CEH       | 00H         | SIMD_INSTR_RETired         | SIMD Instructions retired                                        | This event counts the number of retired SIMD instructions that use MMX registers.                                                                                                                                                                                                                                                                                                                                                                                                                       |
| CFH       | 00H         | SIMD_SAT_INSTR_RETired     | Saturated arithmetic instructions retired                        | This event counts the number of saturated arithmetic SIMD instructions that retired.                                                                                                                                                                                                                                                                                                                                                                                                                    |

**Table A-10. Non-Architectural Performance Events  
in Processors Based on Intel Core Microarchitecture (Contd.)**

| Event Num | Umask Value | Event Name                 | Definition                    | Description and Comment                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|-----------|-------------|----------------------------|-------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| D2H       | 01H         | RAT_STALLS. ROB_READ_PORT  | ROB read port stalls cycles   | <p>This event counts the number of cycles when ROB read port stalls occurred, which did not allow new micro-ops to enter the out-of-order pipeline.</p> <p>Note that, at this stage in the pipeline, additional stalls may occur at the same cycle and prevent the stalled micro-ops from entering the pipe. In such a case, micro-ops retry entering the execution pipe in the next cycle and the ROB-read-port stall is counted again.</p>                                 |
| D2H       | 02H         | RAT_STALLS. PARTIAL_CYCLES | Partial register stall cycles | <p>This event counts the number of cycles instruction execution latency became longer than the defined latency because the instruction uses a register that was partially written by previous instructions.</p>                                                                                                                                                                                                                                                              |
| D2H       | 04H         | RAT_STALLS. FLAGS          | Flag stall cycles             | <p>This event counts the number of cycles during which execution stalled due to several reasons, one of which is a partial flag register stall.</p> <p>A partial register stall may occur when two conditions are met:</p> <ul style="list-style-type: none"> <li>an instruction modifies some, but not all, of the flags in the flag register</li> <li>the next instruction, which depends on flags, depends on flags that were not modified by this instruction</li> </ul> |
| D2H       | 08H         | RAT_STALLS. FPSW           | FPU status word stall         | <p>This event indicates that the FPU status word (FPSW) is written. To obtain the number of times the FPSW is written divide the event count by 2.</p> <p>The FPSW is written by instructions with long latency; a small count may indicate a high penalty.</p>                                                                                                                                                                                                              |
| D2H       | 0FH         | RAT_STALLS. ANY            | All RAT stall cycles          | <p>This event counts the number of stall cycles due to conditions described by:</p> <ul style="list-style-type: none"> <li>RAT_STALLS.ROB_READ_PORT</li> <li>RAT_STALLS.PARTIAL</li> <li>RAT_STALLS.FLAGS</li> <li>RAT_STALLS.FPSW.</li> </ul>                                                                                                                                                                                                                               |

## PERFORMANCE-MONITORING EVENTS

**Table A-10. Non-Architectural Performance Events  
in Processors Based on Intel Core Microarchitecture (Contd.)**

| Event Num | Umask Value | Event Name            | Definition                             | Description and Comment                                                                                                                                                                                                                                                                                  |
|-----------|-------------|-----------------------|----------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| D4H       | 01H         | SEG_RENAME_STALLS.ES  | Segment rename stalls - ES             | This event counts the number of stalls due to the lack of renaming resources for the ES segment register. If a segment is renamed, but not retired and a second update to the same segment occurs, a stall occurs in the front-end of the pipeline until the renamed segment retires.                    |
| D4H       | 02H         | SEG_RENAME_STALLS.DS  | Segment rename stalls - DS             | This event counts the number of stalls due to the lack of renaming resources for the DS segment register. If a segment is renamed, but not retired and a second update to the same segment occurs, a stall occurs in the front-end of the pipeline until the renamed segment retires.                    |
| D4H       | 04H         | SEG_RENAME_STALLS.FS  | Segment rename stalls - FS             | This event counts the number of stalls due to the lack of renaming resources for the FS segment register.<br>If a segment is renamed, but not retired and a second update to the same segment occurs, a stall occurs in the front-end of the pipeline until the renamed segment retires.                 |
| D4H       | 08H         | SEG_RENAME_STALLS.GS  | Segment rename stalls - GS             | This event counts the number of stalls due to the lack of renaming resources for the GS segment register.<br>If a segment is renamed, but not retired and a second update to the same segment occurs, a stall occurs in the front-end of the pipeline until the renamed segment retires.                 |
| D4H       | 0FH         | SEG_RENAME_STALLS.ANY | Any (ES/DS/FS/GS) segment rename stall | This event counts the number of stalls due to the lack of renaming resources for the ES, DS, FS, and GS segment registers.<br>If a segment is renamed but not retired and a second update to the same segment occurs, a stall occurs in the front-end of the pipeline until the renamed segment retires. |
| D5H       | 01H         | SEG_REG_RENAMES.ES    | Segment renames - ES                   | This event counts the number of times the ES segment register is renamed.                                                                                                                                                                                                                                |

**Table A-10. Non-Architectural Performance Events  
in Processors Based on Intel Core Microarchitecture (Contd.)**

| Event Num | Umask Value | Event Name               | Definition                       | Description and Comment                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|-----------|-------------|--------------------------|----------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| D5H       | 02H         | SEG_REG_RENAMES.DS       | Segment renames - DS             | This event counts the number of times the DS segment register is renamed.                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| D5H       | 04H         | SEG_REG_RENAMES.FS       | Segment renames - FS             | This event counts the number of times the FS segment register is renamed.                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| D5H       | 08H         | SEG_REG_RENAMES.GS       | Segment renames - GS             | This event counts the number of times the GS segment register is renamed.                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| D5H       | 0FH         | SEG_REG_RENAMES.ANY      | Any (ES/DS/FS/GS) segment rename | This event counts the number of times any of the four segment registers (ES/DS/FS/GS) is renamed.                                                                                                                                                                                                                                                                                                                                                                                                                         |
| DCH       | 01H         | RESOURCE_STALLS.ROB_FULL | Cycles during which the ROB full | <p>This event counts the number of cycles when the number of instructions in the pipeline waiting for retirement reaches the limit the processor can handle.</p> <p>A high count for this event indicates that there are long latency operations in the pipe (possibly load and store operations that miss the L2 cache, and other instructions that depend on these cannot execute until the former instructions complete execution). In this situation new instructions can not enter the pipe and start execution.</p> |
| DCH       | 02H         | RESOURCE_STALLS.RS_FULL  | Cycles during which the RS full  | <p>This event counts the number of cycles when the number of instructions in the pipeline waiting for execution reaches the limit the processor can handle.</p> <p>A high count of this event indicates that there are long latency operations in the pipe (possibly load and store operations that miss the L2 cache, and other instructions that depend on these cannot execute until the former instructions complete execution). In this situation new instructions can not enter the pipe and start execution.</p>   |

## PERFORMANCE-MONITORING EVENTS

**Table A-10. Non-Architectural Performance Events  
in Processors Based on Intel Core Microarchitecture (Contd.)**

| Event Num | Umask Value | Event Name                    | Definition                                                                                        | Description and Comment                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|-----------|-------------|-------------------------------|---------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| DCH       | 04          | RESOURCE_STALLS.LD_ST         | Cycles during which the pipeline has exceeded load or store limit or waiting to commit all stores | <p>This event counts the number of cycles while resource-related stalls occur due to:</p> <ul style="list-style-type: none"> <li>▪ The number of load instructions in the pipeline reached the limit the processor can handle. The stall ends when a loading instruction retires.</li> <li>▪ The number of store instructions in the pipeline reached the limit the processor can handle. The stall ends when a storing instruction commits its data to the cache or memory.</li> <li>▪ There is an instruction in the pipe that can be executed only when all previous stores complete and their data is committed in the caches or memory. For example, the SFENCE and MFENCE instructions require this behavior.</li> </ul> |
| DCH       | 08H         | RESOURCE_STALLS.FPCW          | Cycles stalled due to FPU control word write                                                      | This event counts the number of cycles while execution was stalled due to writing the floating-point unit (FPU) control word.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| DCH       | 10H         | RESOURCE_STALLS.BR_MISS_CLEAR | Cycles stalled due to branch misprediction                                                        | This event counts the number of cycles after a branch misprediction is detected at execution until the branch and all older micro-ops retire. During this time new micro-ops cannot enter the out-of-order pipeline.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| DCH       | 1FH         | RESOURCE_STALLS.ANY           | Resource related stalls                                                                           | <p>This event counts the number of cycles while resource-related stalls occurs for any conditions described by the following events:</p> <ul style="list-style-type: none"> <li>▪ RESOURCE_STALLS.ROB_FULL</li> <li>▪ RESOURCE_STALLS.RS_FULL</li> <li>▪ RESOURCE_STALLS.LD_ST</li> <li>▪ RESOURCE_STALLS.FPCW</li> <li>▪ RESOURCE_STALLS.BR_MISS_CLEAR</li> </ul>                                                                                                                                                                                                                                                                                                                                                             |
| EOH       | 00H         | BR_INST_DECODED               | Branch instructions decoded                                                                       | This event counts the number of branch instructions decoded.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

in Processors Based on Intel Core Microarchitecture (Contd.)**

| Event Num | Umask Value | Event Name    | Definition                          | Description and Comment                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|-----------|-------------|---------------|-------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| E4H       | 00H         | BOGUS_BR      | Bogus branches                      | <p>This event counts the number of byte sequences that were mistakenly detected as taken branch instructions.</p> <p>This results in a BACLEAR event. This occurs mainly after task switches.</p>                                                                                                                                                                                                                                                           |
| E6H       | 00H         | BACLEAR_S     | BACLEAR asserted                    | <p>This event counts the number of times the front end is resteered, mainly when the BPU cannot provide a correct prediction and this is corrected by other branch handling mechanisms at the front end. This can occur if the code has many branches such that they cannot be consumed by the BPU.</p> <p>Each BACLEAR asserted costs approximately 7 cycles of instruction fetch. The effect on total execution time depends on the surrounding code.</p> |
| F0        | 00H         | PREF_RQSTS_UP | Upward prefetches issued from DPL   | <p>This event counts the number of upward prefetches issued from the Data Prefetch Logic (DPL) to the L2 cache. A prefetch request issued to the L2 cache cannot be cancelled and the requested cache line is fetched to the L2 cache.</p>                                                                                                                                                                                                                  |
| F8        | 00H         | PREF_RQSTS_DN | Downward prefetches issued from DPL | <p>This event counts the number of downward prefetches issued from the Data Prefetch Logic (DPL) to the L2 cache. A prefetch request issued to the L2 cache cannot be cancelled and the requested cache line is fetched to the L2 cache.</p>                                                                                                                                                                                                                |

## A.7 PERFORMANCE MONITORING EVENTS FOR INTEL® ATOM™ PROCESSORS

Processors based on the Intel Atom microarchitecture support the architectural and non-architectural performance-monitoring events listed in Table A-1 and Table A-10. In addition, they also support the following non-architectural performance-monitoring events listed in Table A-11.

**Table A-11. Non-Architectural Performance Events for Intel Atom Processors**

| Event Num. | Umask Value | Event Name            | Definition                                                                      | Description and Comment                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|------------|-------------|-----------------------|---------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 02H        | 81H         | STORE_FORWARDED.GOOD  | Good store forwards                                                             | This event counts the number of times store data was forwarded directly to a load.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| 06H        | 00H         | SEGMENT_REG_LOADS.ANY | Number of segment register loads                                                | This event counts the number of segment register load operations. Instructions that load new values into segment registers cause a penalty. This event indicates performance issues in 16-bit code. If this event occurs frequently, it may be useful to calculate the number of instructions retired per segment register load. If the resulting calculation is low (on average a small number of instructions are executed between segment register loads), then the code's segment register usage should be optimized.<br><br>As a result of branch misprediction, this event is speculative and may include segment register loads that do not actually occur. However, most segment register loads are internally serialized and such speculative effects are minimized. |
| 07H        | 01H         | PREFETCH.PREFETCHTO   | Streaming SIMD Extensions (SSE) PrefetchT0 instructions executed.               | This event counts the number of times the SSE instruction prefetchT0 is executed. This instruction prefetches the data to the L1 data cache and L2 cache.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| 07H        | 06H         | PREFETCH.SW_L2        | Streaming SIMD Extensions (SSE) PrefetchT1 and PrefetchT2 instructions executed | This event counts the number of times the SSE instructions prefetchT1 and prefetchT2 are executed. These instructions prefetch the data to the L2 cache.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

Table A-11. Non-Architectural Performance Events for Intel Atom Processors

| Event Num. | Umask Value | Event Name                     | Definition                                                         | Description and Comment                                                                                                                                                                                                                                                                                                                           |
|------------|-------------|--------------------------------|--------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 07H        | 08H         | PREFETCH.PREFETCHNTA           | Streaming SIMD Extensions (SSE) Prefetch NTA instructions executed | This event counts the number of times the SSE instruction prefetchNTA is executed. This instruction prefetches the data to the L1 data cache.                                                                                                                                                                                                     |
| 08H        | 07H         | DATA_TLB_MISSES.DTLB_MISS      | Memory accesses that missed the DTLB                               | This event counts the number of Data Table Lookaside Buffer (DTLB) misses. The count includes misses detected as a result of speculative accesses. Typically a high count for this event indicates that the code accesses a large number of data pages.                                                                                           |
| 08H        | 05H         | DATA_TLB_MISSES.DTLB_MISS_LD   | DTLB misses due to load operations                                 | This event counts the number of Data Table Lookaside Buffer (DTLB) misses due to load operations. This count includes misses detected as a result of speculative accesses.                                                                                                                                                                        |
| 08H        | 09H         | DATA_TLB_MISSES.LO_DTLB_ISS_LD | LO_DTLB misses due to load operations                              | This event counts the number of LO_DTLB misses due to load operations. This count includes misses detected as a result of speculative accesses.                                                                                                                                                                                                   |
| 08H        | 06H         | DATA_TLB_MISSES.DTLB_MISS_ST   | DTLB misses due to store operations                                | This event counts the number of Data Table Lookaside Buffer (DTLB) misses due to store operations. This count includes misses detected as a result of speculative accesses.                                                                                                                                                                       |
| 0CH        | 03H         | PAGE_WALKS.WALKS               | Number of page-walks executed                                      | This event counts the number of page-walks executed due to either a DTLB or ITLB miss. The page walk duration, PAGE_WALKS.CYCLES, divided by number of page walks is the average duration of a page walk. This can hint to whether most of the page-walks are satisfied by the caches or cause an L2 cache miss.<br>Edge trigger bit must be set. |

## PERFORMANCE-MONITORING EVENTS

**Table A-11. Non-Architectural Performance Events for Intel Atom Processors**

| Event Num. | Umask Value | Event Name               | Definition                                      | Description and Comment                                                                                                                                                                                                                                                                                                                                                 |
|------------|-------------|--------------------------|-------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0CH        | 03H         | PAGE_WALKS.CYCLES        | Duration of page-walks in core cycles           | This event counts the duration of page-walks in core cycles. The paging mode in use typically affects the duration of page walks. Page walk duration divided by number of page walks is the average duration of page-walks. This can hint at whether most of the page-walks are satisfied by the caches or cause an L2 cache miss.<br>Edge trigger bit must be cleared. |
| 10H        | 01H         | X87_COMP_OP.S_EXE.ANY.S  | Floating point computational micro-ops executed | This event counts the number of x87 floating point computational micro-ops executed.                                                                                                                                                                                                                                                                                    |
| 10H        | 81H         | X87_COMP_OP.S_EXE.ANY.AR | Floating point computational micro-ops retired  | This event counts the number of x87 floating point computational micro-ops retired.                                                                                                                                                                                                                                                                                     |
| 11H        | 01H         | FP_ASSIST                | Floating point assists                          | This event counts the number of floating point operations executed that required micro-code assist intervention. These assists are required in the following cases:<br>X87 instructions:<br>1. NaN or denormal are loaded to a register or used as input from memory<br>2. Division by 0<br>3. Underflow output                                                         |
| 11H        | 81H         | FP_ASSIST.AR             | Floating point assists                          | This event counts the number of floating point operations executed that required micro-code assist intervention. These assists are required in the following cases:<br>X87 instructions:<br>1. NaN or denormal are loaded to a register or used as input from memory<br>2. Division by 0<br>3. Underflow output                                                         |
| 12H        | 01H         | MUL.S                    | Multiply operations executed                    | This event counts the number of multiply operations executed. This includes integer as well as floating point multiply operations.                                                                                                                                                                                                                                      |

**Table A-11. Non-Architectural Performance Events for Intel Atom Processors**

| Event Num. | Umask Value                   | Event Name      | Definition                           | Description and Comment                                                                                                                                                                                                                                                                                                                                                                                                                |
|------------|-------------------------------|-----------------|--------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 12H        | 81H                           | MUL.AR          | Multiply operations retired          | This event counts the number of multiply operations retired. This includes integer as well as floating point multiply operations.                                                                                                                                                                                                                                                                                                      |
| 13H        | 01H                           | DIV.S           | Divide operations executed           | This event counts the number of divide operations executed. This includes integer divides, floating point divides and square-root operations executed.                                                                                                                                                                                                                                                                                 |
| 13H        | 81H                           | DIV.AR          | Divide operations retired            | This event counts the number of divide operations retired. This includes integer divides, floating point divides and square-root operations executed.                                                                                                                                                                                                                                                                                  |
| 14H        | 01H                           | CYCLES_DIV_BUSY | Cycles the driver is busy            | This event counts the number of cycles the divider is busy executing divide or square root operations. The divide can be integer, X87 or Streaming SIMD Extensions (SSE). The square root operation can be either X87 or SSE.                                                                                                                                                                                                          |
| 21H        | See Table 30-2                | L2_ADS          | Cycles L2 address bus is in use      | This event counts the number of cycles the L2 address bus is being used for accesses to the L2 cache or bus queue.<br>This event can count occurrences for this core or both cores.                                                                                                                                                                                                                                                    |
| 22H        | See Table 30-2                | L2_DBUS_BUSY    | Cycles the L2 cache data bus is busy | This event counts core cycles during which the L2 cache data bus is busy transferring data from the L2 cache to the core. It counts for all L1 cache misses (data and instruction) that hit the L2 cache. The count will increment by two for a full cache-line request.                                                                                                                                                               |
| 24H        | See Table 30-2 and Table 30-4 | L2_LINES_IN     | L2 cache misses                      | This event counts the number of cache lines allocated in the L2 cache. Cache lines are allocated in the L2 cache as a result of requests from the L1 data and instruction caches and the L2 hardware prefetchers to cache lines that are missing in the L2 cache.<br>This event can count occurrences for this core or both cores. This event can also count demand requests and L2 hardware prefetch requests together or separately. |

## PERFORMANCE-MONITORING EVENTS

**Table A-11. Non-Architectural Performance Events for Intel Atom Processors**

| Event Num. | Umask Value                   | Event Name     | Definition                               | Description and Comment                                                                                                                                                                                                                                                                                                                                              |
|------------|-------------------------------|----------------|------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 25H        | See Table 30-2                | L2_M_LINES_IN  | L2 cache line modifications              | This event counts whenever a modified cache line is written back from the L1 data cache to the L2 cache.<br>This event can count occurrences for this core or both cores.                                                                                                                                                                                            |
| 26H        | See Table 30-2 and Table 30-4 | L2_LINES_OUT   | L2 cache lines evicted                   | This event counts the number of L2 cache lines evicted.<br>This event can count occurrences for this core or both cores. This event can also count evictions due to demand requests and L2 hardware prefetch requests together or separately.                                                                                                                        |
| 27H        | See Table 30-2 and Table 30-4 | L2_M_LINES_OUT | Modified lines evicted from the L2 cache | This event counts the number of L2 modified cache lines evicted. These lines are written back to memory unless they also exist in a shared-state in one of the L1 data caches.<br>This event can count occurrences for this core or both cores. This event can also count evictions due to demand requests and L2 hardware prefetch requests together or separately. |
| 28H        | See Table 30-2 and Table 30-5 | L2_IFETCH      | L2 cacheable instruction fetch requests  | This event counts the number of instruction cache line requests from the ICache. It does not include fetch requests from uncacheable memory. It does not include ITLB miss accesses.<br>This event can count occurrences for this core or both cores. This event can also count accesses to cache lines at different MESI states.                                    |

**Table A-11. Non-Architectural Performance Events for Intel Atom Processors**

| Event Num. | Umask Value                               | Event Name | Definition         | Description and Comment                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

| 2EH        | 41H                                       | L2_RQSTS.SELF_DEMAND.I_STAT_E | L2 cache demand requests from this core that miss the L2 cache. This includes L1 data cache reads, writes, and locked accesses, L1 data prefetch requests, and instruction fetches. | This event counts all completed L2 cache demand requests from this core that miss the L2 cache. This includes L1 data cache reads, writes, and locked accesses, L1 data prefetch requests, and instruction fetches.<br><b>This is an architectural performance event.</b>                                                                                                                                                                                                                                                                                                                                                                                                  |
| 2EH        | 4FH                                       | L2_RQSTS.SELF_DEMAND.MESI     | L2 cache demand requests from this core                                                                                                                                             | This event counts all completed L2 cache demand requests from this core. This includes L1 data cache reads, writes, and locked accesses, L1 data prefetch requests, and instruction fetches.<br><b>This is an architectural performance event.</b>                                                                                                                                                                                                                                                                                                                                                                                                                         |
| 30H        | See Table 30-2, Table 30-4 and Table 30-5 | L2_REJECT_BUS_Q               | Rejected L2 cache requests                                                                                                                                                          | This event indicates that a pending L2 cache request that requires a bus transaction is delayed from moving to the bus queue. Some of the reasons for this event are:<br><ul style="list-style-type: none"> <li>- The bus queue is full.</li> <li>- The bus queue already holds an entry for a cache line in the same set.</li> </ul> The number of events is greater or equal to the number of requests that were rejected. <ul style="list-style-type: none"> <li>- for this core or both cores.</li> <li>- due to demand requests and L2 hardware prefetch requests together, or separately.</li> <li>- of accesses to cache lines at different MESI states.</li> </ul> |
| 32H        | See Table 30-2                            | L2_NO_REQ                     | Cycles no L2 cache requests are pending                                                                                                                                             | This event counts the number of cycles that no L2 cache requests are pending.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| 3AH        | 00H                                       | EIST_TRANS                    | Number of Enhanced Intel SpeedStep(R) Technology (EIST) transitions                                                                                                                 | This event counts the number of Enhanced Intel SpeedStep(R) Technology (EIST) transitions that include a frequency change, either with or without VID change. This event is incremented only while the counting core is in CO state. Since the CxE states include an EIST transition, the event will be incremented accordingly.                                                                                                                                                                                                                                                                                                                                           |

Table A-11. Non-Architectural Performance Events for Intel Atom Processors

| Event Num. | Umask Value | Event Name              | Definition                          | Description and Comment                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|------------|-------------|-------------------------|-------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|            |             |                         |                                     | EIST transitions are commonly initiated by OS, but can be initiated by HW internally. For example: CxE states are C-states (C1,C2,C3...) which not only place the CPU into a sleep state by turning off the clock and other components, but also lower the voltage (which reduces the leakage power consumption). The same is true for thermal throttling transition which uses EIST internally.                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| 3BH        | COH         | THERMAL_TRIP            | Number of thermal trips             | This event counts the number of thermal trips. A thermal trip occurs whenever the processor temperature exceeds the thermal trip threshold temperature. Following a thermal trip, the processor automatically reduces frequency and voltage. The processor checks the temperature every millisecond, and returns to normal when the temperature falls below the thermal trip threshold temperature.                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| 3CH        | 00H         | CPU_CLK_UNHALTED.CORE_P | Core cycles when core is not halted | This event counts the number of core cycles while the core is not in a halt state. The core enters the halt state when it is running the HLT instruction. This event is a component in many key event ratios.<br><br>In mobile systems the core frequency may change from time to time. For this reason this event may have a changing ratio with regards to time. In systems with a constant core frequency, this event can give you a measurement of the elapsed time while the core was not in halt state by dividing the event count by the core frequency.<br><br>-This is an architectural performance event.<br>- The event CPU_CLK_UNHALTED.CORE_P is counted by a programmable counter.<br>- The event CPU_CLK_UNHALTED.CORE is counted by a designated fixed counter, leaving the two programmable counters available for other events. |

## PERFORMANCE-MONITORING EVENTS

**Table A-11. Non-Architectural Performance Events for Intel Atom Processors**

| Event Num. | Umask Value                   | Event Name                | Definition                                             | Description and Comment                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|------------|-------------------------------|---------------------------|--------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 3CH        | 01H                           | CPU_CLK_UNHALTED.BUS      | Bus cycles when core is not halted                     | <p>This event counts the number of bus cycles while the core is not in the halt state. This event can give you a measurement of the elapsed time while the core was not in the halt state, by dividing the event count by the bus frequency. The core enters the halt state when it is running the HLT instruction.</p> <p>The event also has a constant ratio with CPU_CLK_UNHALTED.REF event, which is the maximum bus to processor frequency ratio. Non-halted bus cycles are a component in many key event ratios.</p> |
| 3CH        | 02H                           | CPU_CLK_UNHALTED.NO_OTHER | Bus cycles when core is active and the other is halted | <p>This event counts the number of bus cycles during which the core remains non-halted, and the other core on the processor is halted.</p> <p>This event can be used to determine the amount of parallelism exploited by an application or a system. Divide this event count by the bus frequency to determine the amount of time that only one core was in use.</p>                                                                                                                                                       |
| 40H        | 21H                           | L1D_CACHE.LD              | L1 Cacheable Data Reads                                | This event counts the number of data reads from cacheable memory.                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| 40H        | 22H                           | L1D_CACHE.ST              | L1 Cacheable Data Writes                               | This event counts the number of data writes to cacheable memory.                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| 60H        | See Table 30-2 and Table 30-3 | BUS_REQUEST_OUTSTANDING   | Outstanding cacheable data read bus requests duration  | This event counts the number of pending full cache line read transactions on the bus occurring in each cycle. A read transaction is pending from the cycle it is sent on the bus until the full cache line is received by the processor. NOTE: This event is thread-independent and will not provide a count per logical processor when AnyThr is disabled.                                                                                                                                                                |

Table A-11. Non-Architectural Performance Events for Intel Atom Processors

| Event Num. | Umask Value                   | Event Name      | Definition                                     | Description and Comment                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|------------|-------------------------------|-----------------|------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 61H        | See Table 30-3                | BUS_BNR_DRV     | Number of Bus Not Ready (BNR) signals asserted | <p>This event counts the number of Bus Not Ready (BNR) signals that the processor asserts on the bus to suspend additional bus requests by other bus agents. A bus agent asserts the BNR signal when the number of data and snoop transactions is close to the maximum that the bus can handle.</p> <p>While this signal is asserted, new transactions cannot be submitted on the bus. As a result, transaction latency may have higher impact on program performance.</p> <p><b>NOTE:</b> This event is thread-independent and will not provide a count per logical processor when AnyThr is disabled.</p> |
| 62H        | See Table 30-3                | BUS_DRDY_CLOCKS | Bus cycles when data is sent on the bus        | <p>This event counts the number of bus cycles during which the DRDY (Data Ready) signal is asserted on the bus. The DRDY signal is asserted when data is sent on the bus.</p> <p>This event counts the number of bus cycles during which this agent (the processor) writes data on the bus back to memory or to other bus agents. This includes all explicit and implicit data writebacks, as well as partial writes.</p> <p><b>NOTE:</b> This event is thread-independent and will not provide a count per logical processor when AnyThr is disabled.</p>                                                  |
| 63H        | See Table 30-2 and Table 30-3 | BUS_LOCK_CLOCKS | Bus cycles when a LOCK signal is asserted.     | <p>This event counts the number of bus cycles, during which the LOCK signal is asserted on the bus. A LOCK signal is asserted when there is a locked memory access, due to:</p> <ul style="list-style-type: none"> <li>- Uncacheable memory</li> <li>- Locked operation that spans two cache lines</li> <li>- Page-walk from an uncacheable page table.</li> </ul> <p>Bus locks have a very high performance penalty and it is highly recommended to avoid such accesses. <b>NOTE:</b> This event is thread-independent and will not provide a count per logical processor when AnyThr is disabled.</p>     |

## PERFORMANCE-MONITORING EVENTS

**Table A-11. Non-Architectural Performance Events for Intel Atom Processors**

| Event Num. | Umask Value                   | Event Name       | Definition                               | Description and Comment                                                                                                                                                                                                                                                            |
|------------|-------------------------------|------------------|------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 64H        | See Table 30-2                | BUS_DATA_RCV     | Bus cycles while processor receives data | This event counts the number of cycles during which the processor is busy receiving data. NOTE: This event is thread-independent and will not provide a count per logical processor when AnyThr is disabled.                                                                       |
| 65H        | See Table 30-2 and Table 30-3 | BUS_TRANS_BRD    | Burst read bus transactions              | This event counts the number of burst read transactions including:<br>- L1 data cache read misses (and L1 data cache hardware prefetches)<br>- L2 hardware prefetches by the DPL and L2 streamer<br>- IFU read misses of cacheable lines.<br>It does not include RFO transactions. |
| 66H        | See Table 30-2 and Table 30-3 | BUS_TRANS_RFO    | RFO bus transactions                     | This event counts the number of Read For Ownership (RFO) bus transactions, due to store operations that miss the L1 data cache and the L2 cache. This event also counts RFO bus transactions due to locked operations.                                                             |
| 67H        | See Table 30-2 and Table 30-3 | BUS_TRANS_WB     | Explicit writeback bus transactions      | This event counts all explicit writeback bus transactions due to dirty line evictions. It does not count implicit writebacks due to invalidation by a snoop request.                                                                                                               |
| 68H        | See Table 30-2 and Table 30-3 | BUS_TRANS_IFETCH | Instruction-fetch bus transactions.      | This event counts all instruction fetch full cache line bus transactions.                                                                                                                                                                                                          |
| 69H        | See Table 30-2 and Table 30-3 | BUS_TRANS_INVAL  | Invalidate bus transactions              | This event counts all invalidate transactions. Invalidate transactions are generated when:<br>- A store operation hits a shared line in the L2 cache.<br>- A full cache line write misses the L2 cache or hits a shared line in the L2 cache.                                      |

**Table A-11. Non-Architectural Performance Events for Intel Atom Processors**

| Event Num. | Umask Value                   | Event Name      | Definition                                | Description and Comment                                                                                                                                                                                                                    |
|------------|-------------------------------|-----------------|-------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 6AH        | See Table 30-2 and Table 30-3 | BUS_TRANS_PWR   | Partial write bus transaction.            | This event counts partial write bus transactions.                                                                                                                                                                                          |
| 6BH        | See Table 30-2 and Table 30-3 | BUS_TRANS_P     | Partial bus transactions                  | This event counts all (read and write) partial bus transactions.                                                                                                                                                                           |
| 6CH        | See Table 30-2 and Table 30-3 | BUS_TRANS_IO    | IO bus transactions                       | This event counts the number of completed I/O bus transactions as a result of IN and OUT instructions. The count does not include memory mapped IO.                                                                                        |
| 6DH        | See Table 30-2 and Table 30-3 | BUS_TRANS_DEF   | Deferred bus transactions                 | This event counts the number of deferred transactions.                                                                                                                                                                                     |
| 6EH        | See Table 30-2 and Table 30-3 | BUS_TRANS_BURST | Burst (full cache-line) bus transactions. | This event counts burst (full cache line) transactions including:<br>- Burst reads<br>- RFOs<br>- Explicit writebacks<br>- Write combine lines                                                                                             |
| 6FH        | See Table 30-2 and Table 30-3 | BUS_TRANS_MEM   | Memory bus transactions                   | This event counts all memory bus transactions including:<br>- burst transactions<br>- partial reads and writes<br>- invalidate transactions<br><br>The BUS_TRANS_MEM count is the sum of BUS_TRANS_BURST, BUS_TRANS_P and BUS_TRANS_INVAL. |

## PERFORMANCE-MONITORING EVENTS

**Table A-11. Non-Architectural Performance Events for Intel Atom Processors**

| Event Num. | Umask Value                   | Event Name      | Definition             | Description and Comment                                                                                                                                                                                                                                                                                             |
|------------|-------------------------------|-----------------|------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 70H        | See Table 30-2 and Table 30-3 | BUS_TRANS_A_NY  | All bus transactions   | This event counts all bus transactions. This includes:<br>- Memory transactions<br>- IO transactions (non memory-mapped)<br>- Deferred transaction completion<br>- Other less frequent transactions, such as interrupts                                                                                             |
| 77H        | See Table 30-2 and Table 30-5 | EXT_SNOOP       | External snoops        | This event counts the snoop responses to bus transactions. Responses can be counted separately by type and by bus agent. NOTE: This event is thread-independent and will not provide a count per logical processor when AnyThr is disabled.                                                                         |
| 7AH        | See Table 30-3                | BUS_HIT_DRV     | HIT signal asserted    | This event counts the number of bus cycles during which the processor drives the HIT# pin to signal HIT snoop response. NOTE: This event is thread-independent and will not provide a count per logical processor when AnyThr is disabled.                                                                          |
| 7BH        | See Table 30-3                | BUS_HITM_DRV    | HITM signal asserted   | This event counts the number of bus cycles during which the processor drives the HITM# pin to signal HITM snoop response. NOTE: This event is thread-independent and will not provide a count per logical processor when AnyThr is disabled.                                                                        |
| 7DH        | See Table 30-2                | BUSQ_EMPTY      | Bus queue is empty     | This event counts the number of cycles during which the core did not have any pending transactions in the bus queue.<br><b>NOTE:</b> This event is thread-independent and will not provide a count per logical processor when AnyThr is disabled.                                                                   |
| 7EH        | See Table 30-2 and Table 30-3 | SNOOP_STALL_DRV | Bus stalled for snoops | This event counts the number of times that the bus snoop stall signal is asserted. During the snoop stall cycles no new bus transactions requiring a snoop response can be initiated on the bus. NOTE: This event is thread-independent and will not provide a count per logical processor when AnyThr is disabled. |

**Table A-11. Non-Architectural Performance Events for Intel Atom Processors**

| Event Num. | Umask Value    | Event Name               | Definition                                   | Description and Comment                                                                                                                                                                                                                 |
|------------|----------------|--------------------------|----------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7FH        | See Table 30-2 | BUS_IO_WAIT              | IO requests waiting in the bus queue         | This event counts the number of core cycles during which IO requests wait in the bus queue. This event counts IO requests from the core.                                                                                                |
| 80H        | 03H            | ICACHE.ACCESS_ES         | Instruction fetches                          | This event counts all instruction fetches, including uncacheable fetches.                                                                                                                                                               |
| 80H        | 02H            | ICACHE.MISSES            | Icache miss                                  | This event counts all instruction fetches that miss the Instruction cache or produce memory requests. This includes uncacheable fetches. An instruction fetch miss is counted only once and not once for every cycle it is outstanding. |
| 82H        | 04H            | ITLB.FLUSH               | ITLB flushes                                 | This event counts the number of ITLB flushes.                                                                                                                                                                                           |
| 82H        | 02H            | ITLB.MISSES              | ITLB misses                                  | This event counts the number of instruction fetches that miss the ITLB.                                                                                                                                                                 |
| AAH        | 02H            | MACRO_INSTS.CISC_DECODED | CISC macro instructions decoded              | This event counts the number of complex instructions decoded, but not necessarily executed or retired. Only one complex instruction can be decoded at a time.                                                                           |
| AAH        | 03H            | MACRO_INSTS.ALL_DECODED  | All Instructions decoded                     | This event counts the number of instructions decoded.                                                                                                                                                                                   |
| BOH        | 00H            | SIMD_UOPS_EX_ECS         | SIMD micro-ops executed (excluding stores)   | This event counts all the SIMD micro-ops executed. This event does not count MOVO and MOVD stores from register to memory.                                                                                                              |
| BOH        | 80H            | SIMD_UOPS_EX_EAR         | SIMD micro-ops retired (excluding stores)    | This event counts the number of SIMD saturated arithmetic micro-ops executed.                                                                                                                                                           |
| B1H        | 00H            | SIMD_SAT_UOP_EXEC_S      | SIMD saturated arithmetic micro-ops executed | This event counts the number of SIMD saturated arithmetic micro-ops executed.                                                                                                                                                           |
| B1H        | 80H            | SIMD_SAT_UOP_EXEC_AR     | SIMD saturated arithmetic micro-ops retired  | This event counts the number of SIMD saturated arithmetic micro-ops retired.                                                                                                                                                            |

## PERFORMANCE-MONITORING EVENTS

**Table A-11. Non-Architectural Performance Events for Intel Atom Processors**

| Event Num. | Umask Value | Event Name                       | Definition                                | Description and Comment                                                    |
|------------|-------------|----------------------------------|-------------------------------------------|----------------------------------------------------------------------------|
| B3H        | 01H         | SIMD_UOP_TYPE_EXEC.MUL.S         | SIMD packed multiply micro-ops executed   | This event counts the number of SIMD packed multiply micro-ops executed.   |
| B3H        | 81H         | SIMD_UOP_TYPE_EXEC.MUL.AR        | SIMD packed multiply micro-ops retired    | This event counts the number of SIMD packed multiply micro-ops retired.    |
| B3H        | 02H         | SIMD_UOP_TYPE_EXEC.SHIFT.S       | SIMD packed shift micro-ops executed      | This event counts the number of SIMD packed shift micro-ops executed.      |
| B3H        | 82H         | SIMD_UOP_TYPE_EXEC.SHIFT.AR      | SIMD packed shift micro-ops retired       | This event counts the number of SIMD packed shift micro-ops retired.       |
| B3H        | 04H         | SIMD_UOP_TYPE_EXEC.PACK.S        | SIMD pack micro-ops executed              | This event counts the number of SIMD pack micro-ops executed.              |
| B3H        | 84H         | SIMD_UOP_TYPE_EXEC.PACK.AR       | SIMD pack micro-ops retired               | This event counts the number of SIMD pack micro-ops retired.               |
| B3H        | 08H         | SIMD_UOP_TYPE_EXEC.UNPACK.S      | SIMD unpack micro-ops executed            | This event counts the number of SIMD unpack micro-ops executed.            |
| B3H        | 88H         | SIMD_UOP_TYPE_EXEC.UNPACK.AR     | SIMD unpack micro-ops retired             | This event counts the number of SIMD unpack micro-ops retired.             |
| B3H        | 10H         | SIMD_UOP_TYPE_EXEC.LOGICAL.S     | SIMD packed logical micro-ops executed    | This event counts the number of SIMD packed logical micro-ops executed.    |
| B3H        | 90H         | SIMD_UOP_TYPE_EXEC.LOGICAL.AR    | SIMD packed logical micro-ops retired     | This event counts the number of SIMD packed logical micro-ops retired.     |
| B3H        | 20H         | SIMD_UOP_TYPE_EXEC.ARITHMETIC.S  | SIMD packed arithmetic micro-ops executed | This event counts the number of SIMD packed arithmetic micro-ops executed. |
| B3H        | A0H         | SIMD_UOP_TYPE_EXEC.ARITHMETIC.AR | SIMD packed arithmetic micro-ops retired  | This event counts the number of SIMD packed arithmetic micro-ops retired.  |

|------------|-------------|----------------------------------------|-----------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| COH        | 00H         | INST_RETIRED.<br>ANY_P                 | Instructions retired (precise event).                     | This event counts the number of instructions that retire execution. For instructions that consist of multiple micro-ops, this event counts the retirement of the last micro-op of the instruction. The counter continues counting during hardware interrupts, traps, and inside interrupt handlers.                                                                                                                                                                                                                                |
| N/A        | 00H         | INST_RETIRED.<br>ANY                   | Instructions retired                                      | This event counts the number of instructions that retire execution. For instructions that consist of multiple micro-ops, this event counts the retirement of the last micro-op of the instruction. The counter continues counting during hardware interrupts, traps, and inside interrupt handlers.                                                                                                                                                                                                                                |
| C2H        | 10H         | UOPS_RETIRED.<br>ANY                   | Micro-ops retired                                         | This event counts the number of micro-ops retired. The processor decodes complex macro instructions into a sequence of simpler micro-ops. Most instructions are composed of one or two micro-ops. Some instructions are decoded into longer sequences such as repeat instructions, floating point transcendental instructions, and assists. In some cases micro-op sequences are fused or whole instructions are fused into one micro-op. See other UOPS_RETIRED events for differentiating retired fused and non-fused micro-ops. |
| C3H        | 01H         | MACHINE_CLEA<br>RS.SMC                 | Self-Modifying Code detected                              | This event counts the number of times that a program writes to a code section. Self-modifying code causes a severe penalty in all Intel® architecture processors.                                                                                                                                                                                                                                                                                                                                                                  |
| C4H        | 00H         | BR_INST_RETIR<br>ED.ANY                | Retired branch instructions                               | This event counts the number of branch instructions retired.<br><b>This is an architectural performance event.</b>                                                                                                                                                                                                                                                                                                                                                                                                                 |
| C4H        | 01H         | BR_INST_RETIR<br>ED.PRED_NOT_<br>TAKEN | Retired branch instructions that were predicted not-taken | This event counts the number of branch instructions retired that were correctly predicted to be not-taken.                                                                                                                                                                                                                                                                                                                                                                                                                         |

| C4H        | 02H         | BR_INST_RETIR ED.MISPRED_N OT_TAKEN | Retired branch instructions that were mispredicted not-taken | This event counts the number of branch instructions retired that were mispredicted and not-taken.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| C4H        | 04H         | BR_INST_RETIR ED.PRED_TAKE N        | Retired branch instructions that were predicted taken        | This event counts the number of branch instructions retired that were correctly predicted to be taken.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| C4H        | 08H         | BR_INST_RETIR ED.MISPRED_TA KEN     | Retired branch instructions that were mispredicted taken     | This event counts the number of branch instructions retired that were mispredicted and taken.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| C4H        | 0AH         | BR_INST_RETIR ED.MISPRED            | Retired mispredicted branch instructions (precise event)     | <p>This event counts the number of retired branch instructions that were mispredicted by the processor. A branch misprediction occurs when the processor predicts that the branch would be taken, but it is not, or vice-versa. Mispredicted branches degrade the performance because the processor starts executing instructions along a wrong path it predicts. When the misprediction is discovered, all the instructions executed in the wrong path must be discarded, and the processor must start again on the correct path.</p> <p>Using the Profile-Guided Optimization (PGO) features of the Intel® C++ compiler may help reduce branch mispredictions. See the compiler documentation for more information on this feature.</p> |

Table A-11. Non-Architectural Performance Events for Intel Atom Processors

| Event Num. | Umask Value | Event Name               | Definition                                                | Description and Comment                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

|            |             |                          |                                                           | <p>To determine the branch misprediction ratio, divide the BR_INST_RETIR.MISPRED event count by the number of BR_INST_RETIR.ANY event count. To determine the number of mispredicted branches per instruction, divide the number of mispredicted branches by the INST_RETIR.ANY event count. To measure the impact of the branch mispredictions use the event RESOURCE_STALLS.BR_MISS_CLEAR.</p> <p><b>Tips</b></p> <ul style="list-style-type: none"> <li>- See the optimization guide for tips on reducing branch mispredictions.</li> <li>- PGO's purpose is to have straight line code for the most frequent execution paths, reducing branches taken and increasing the "basic block" size, possibly also reducing the code footprint or working-set.</li> </ul> |
| C4H        | 0CH         | BR_INST_RETIR.ED.TAKEN   | Retired taken branch instructions                         | This event counts the number of branches retired that were taken.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| C4H        | 0FH         | BR_INST_RETIR.ED.ANY1    | Retired branch instructions                               | This event counts the number of branch instructions retired that were mispredicted. This event is a duplicate of BR_INST_RETIR.MISPRED.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| C5H        | 00H         | BR_INST_RETIR.ED.MISPRED | Retired mispredicted branch instructions (precise event). | This event counts the number of retired branch instructions that were mispredicted by the processor. A branch misprediction occurs when the processor predicts that the branch would be taken, but it is not, or vice-versa. Mispredicted branches degrade the performance because the processor starts executing instructions along a wrong path it predicts. When the misprediction is discovered, all the instructions executed in the wrong path must be discarded, and the processor must start again on the correct path.                                                                                                                                                                                                                                       |

## PERFORMANCE-MONITORING EVENTS

| C7H        | 08H         | SIMD_INST_RETIRED.SCALAR_DOUBLE | Retired Streaming SIMD Extensions 2 (SSE2) scalar-double instructions. | This event counts the number of SSE2 scalar-double instructions retired.                                                                                                                                                                                                                                                         |
| C7H        | 10H         | SIMD_INST_RETIRED.VECTOR        | Retired Streaming SIMD Extensions 2 (SSE2) vector instructions.        | This event counts the number of SSE2 vector instructions retired.                                                                                                                                                                                                                                                                |
| C7H        | 1FH         | SIMD_INST_RETIRED.ANY           | Retired Streaming SIMD instructions                                    | This event counts the overall number of SIMD instructions retired. To count each type of SIMD instruction separately, use the following events:<br>SIMD_INST_RETIRED.PACKED_SINGLE,<br>SIMD_INST_RETIRED.SCALAR_SINGLE,<br>SIMD_INST_RETIRED.PACKED_DOUBLE,<br>SIMD_INST_RETIRED.SCALAR_DOUBLE, and<br>SIMD_INST_RETIRED.VECTOR. |
| C8H        | 00H         | HW_INT_RCV                      | Hardware interrupts received                                           | This event counts the number of hardware interrupts received by the processor. This event will count twice for dual-pipe micro-ops.                                                                                                                                                                                              |

## PERFORMANCE-MONITORING EVENTS

**Table A-11. Non-Architectural Performance Events for Intel Atom Processors**

| Event Num. | Umask Value | Event Name                           | Definition                                                                           | Description and Comment                                                                                                                                                                                                                                                                                           |
|------------|-------------|--------------------------------------|--------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| CAH        | 01H         | SIMD_COMP_IN_ST_RETIREDPACKED_SINGLE | Retired computational Streaming SIMD Extensions (SSE) packed-single instructions.    | This event counts the number of computational SSE packed-single instructions retired. Computational instructions perform arithmetic computations, like add, multiply and divide. Instructions that perform load and store operations or logical operations, like XOR, OR, and AND are not counted by this event.  |
| CAH        | 02H         | SIMD_COMP_IN_ST_RETIREDSALAR_SINGLE  | Retired computational Streaming SIMD Extensions (SSE) scalar-single instructions.    | This event counts the number of computational SSE scalar-single instructions retired. Computational instructions perform arithmetic computations, like add, multiply and divide. Instructions that perform load and store operations or logical operations, like XOR, OR, and AND are not counted by this event.  |
| CAH        | 04H         | SIMD_COMP_IN_ST_RETIREDPACKED_DOUBLE | Retired computational Streaming SIMD Extensions 2 (SSE2) packed-double instructions. | This event counts the number of computational SSE2 packed-double instructions retired. Computational instructions perform arithmetic computations, like add, multiply and divide. Instructions that perform load and store operations or logical operations, like XOR, OR, and AND are not counted by this event. |
| CAH        | 08H         | SIMD_COMP_IN_ST_RETIREDSALAR_DOUBLE  | Retired computational Streaming SIMD Extensions 2 (SSE2) scalar-double instructions  | This event counts the number of computational SSE2 scalar-double instructions retired. Computational instructions perform arithmetic computations, like add, multiply and divide. Instructions that perform load and store operations or logical operations, like XOR, OR, and AND are not counted by this event. |
| CBH        | 01H         | MEM_LOAD_RETIRED.L2_HIT              | Retired loads that hit the L2 cache (precise event)                                  | This event counts the number of retired load operations that missed the L1 data cache and hit the L2 cache.                                                                                                                                                                                                       |
| CBH        | 02H         | MEM_LOAD_RETIRED.L2_MISS             | Retired loads that miss the L2 cache (precise event)                                 | This event counts the number of retired load operations that missed the L2 cache.                                                                                                                                                                                                                                 |

Table A-11. Non-Architectural Performance Events for Intel Atom Processors

| Event Num. | Umask Value | Event Name                 | Definition                                       | Description and Comment                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|------------|-------------|----------------------------|--------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| CBH        | 04H         | MEM_LOAD_RETIRED.DTLB_MISS | Retired loads that miss the DTLB (precise event) | This event counts the number of retired loads that missed the DTLB. The DTLB miss is not counted if the load operation causes a fault.                                                                                                                                                                                                                                                                                                                     |
| CDH        | 00H         | SIMD_ASSIST                | SIMD assists invoked                             | This event counts the number of SIMD assists invoked. SIMD assists are invoked when an EMMS instruction is executed after MMX™ technology code has changed the MMX state in the floating point stack. For example, these assists are required in the following cases:<br>Streaming SIMD Extensions (SSE) instructions:<br>1. Denormal input when the DAZ (Denormals Are Zeros) flag is off<br>2. Underflow result when the FTZ (Flush To Zero) flag is off |
| CEH        | 00H         | SIMD_INSTR_RETIRED         | SIMD Instructions retired                        | This event counts the number of SIMD instructions that retired.                                                                                                                                                                                                                                                                                                                                                                                            |
| CFH        | 00H         | SIMD_SAT_INSTR_RETired     | Saturated arithmetic instructions retired        | This event counts the number of saturated arithmetic SIMD instructions that retired.                                                                                                                                                                                                                                                                                                                                                                       |
| EOH        | 01H         | BR_INST_DECODED            | Branch instructions decoded                      | This event counts the number of branch instructions decoded.                                                                                                                                                                                                                                                                                                                                                                                               |

## PERFORMANCE-MONITORING EVENTS

**Table A-11. Non-Architectural Performance Events for Intel Atom Processors**

| Event Num. | Umask Value | Event Name    | Definition       | Description and Comment                                                                                                                                                                                                                                                                                                                                                                                                              |
|------------|-------------|---------------|------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| E4H        | 01H         | BOGUS_BR      | Bogus branches   | This event counts the number of byte sequences that were mistakenly detected as taken branch instructions. This results in a BACLEAR event and the BTB is flushed. This occurs mainly after task switches.                                                                                                                                                                                                                           |
| E6H        | 01H         | BACLEAR.S.ANY | BACLEAR asserted | This event counts the number of times the front end is redirected for a branch prediction, mainly when an early branch prediction is corrected by other branch handling mechanisms in the front-end. This can occur if the code has many branches such that they cannot be consumed by the branch predictor. Each Baclear asserted costs approximately 7 cycles. The effect on total execution time depends on the surrounding code. |

## A.8 PERFORMANCE MONITORING EVENTS FOR INTEL® CORE™ SOLO AND INTEL® CORE™ DUO PROCESSORS

Table A-12 lists non-architectural performance events for Intel Core Duo processors. If a non-architectural event requires qualification in core specificity, it is indicated in the comment column. Table A-12 also applies to Intel Core Solo processors; bits in the unit mask corresponding to core-specificity are reserved and should be 00B.

**Table A-12. Non-Architectural Performance Events  
in Intel Core Solo and Intel Core Duo Processors**

| Event Num. | Event Mask Mnemonic | Umask Value | Description                                                                                                                                                                                           | Comment         |
|------------|---------------------|-------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------|
| 03H        | LD_Blocks           | 00H         | Load operations delayed due to store buffer blocks.<br><br>The preceding store may be blocked due to unknown address, unknown data, or conflict due to partial overlap between the load and store.    |                 |
| 04H        | SD_Drains           | 00H         | Cycles while draining store buffers.                                                                                                                                                                  |                 |
| 05H        | Misalign_Mem_Ref    | 00H         | Misaligned data memory references (MOB splits of loads and stores).                                                                                                                                   |                 |
| 06H        | Seg_Reg_Loads       | 00H         | Segment register loads.                                                                                                                                                                               |                 |
| 07H        | SSE_PrefNta_Ret     | 00H         | SSE software prefetch instruction PREFETCHNTA retired.                                                                                                                                                |                 |
| 07H        | SSE_PrefT1_Ret      | 01H         | SSE software prefetch instruction PREFETCHT1 retired.                                                                                                                                                 |                 |
| 07H        | SSE_PrefT2_Ret      | 02H         | SSE software prefetch instruction PREFETCHT2 retired.                                                                                                                                                 |                 |
| 07H        | SSE_NTStores_Ret    | 03H         | SSE streaming store instruction retired.                                                                                                                                                              |                 |
| 10H        | FP_Comps_Op_Exe     | 00H         | FP computational Instruction executed. FADD, FSUB, FCOM, FMULs, MUL, IMUL, FDIVs, DIV, IDIV, FPREMs, FSQRT are included; but exclude FADD or FMUL used in the middle of a transcendental instruction. |                 |
| 11H        | FP_Assist           | 00H         | FP exceptions experienced microcode assists.                                                                                                                                                          | IA32_PMC1 only. |

## PERFORMANCE-MONITORING EVENTS

**Table A-12. Non-Architectural Performance Events  
in Intel Core Solo and Intel Core Duo Processors (Contd.)**

| Event Num. | Event Mask Mnemonic | Umask Value                 | Description                                                                        | Comment                                                 |
|------------|---------------------|-----------------------------|------------------------------------------------------------------------------------|---------------------------------------------------------|
| 12H        | Mul                 | 00H                         | Multiply operations (a speculative count, including FP and integer multiplies).    | IA32_PMC1 only.                                         |
| 13H        | Div                 | 00H                         | Divide operations (a speculative count, including FP and integer divisions).       | IA32_PMC1 only.                                         |
| 14H        | Cycles_Div_Busy     | 00H                         | Cycles the divider is busy.                                                        | IA32_PMC0 only.                                         |
| 21H        | L2_ADS              | 00H                         | L2 Address strobes.                                                                | Requires core-specificity                               |
| 22H        | Dbus_Busy           | 00H                         | Core cycle during which data bus was busy (increments by 4).                       | Requires core-specificity                               |
| 23H        | Dbus_Busy_Rd        | 00H                         | Cycles data bus is busy transferring data to a core (increments by 4).             | Requires core-specificity                               |
| 24H        | L2_Lines_In         | 00H                         | L2 cache lines allocated.                                                          | Requires core-specificity and HW prefetch qualification |
| 25H        | L2_M_Lines_In       | 00H                         | L2 Modified-state cache lines allocated.                                           | Requires core-specificity                               |
| 26H        | L2_Lines_Out        | 00H                         | L2 cache lines evicted.                                                            | Requires core-specificity and HW prefetch qualification |
| 27H        | L2_M_Lines_Out      | 00H                         | L2 Modified-state cache lines evicted.                                             |                                                         |
| 28H        | L2_IFetch           | Requires MESI qualification | L2 instruction fetches from instruction fetch unit (includes speculative fetches). | Requires core-specificity                               |
| 29H        | L2_LD               | Requires MESI qualification | L2 cache reads.                                                                    | Requires core-specificity                               |
| 2AH        | L2_ST               | Requires MESI qualification | L2 cache writes (includes speculation).                                            | Requires core-specificity                               |

**Table A-12. Non-Architectural Performance Events  
in Intel Core Solo and Intel Core Duo Processors (Contd.)**

| Event Num. | Event Mask Mnemonic     | Umask Value                 | Description                                                                       | Comment                                              |
|------------|-------------------------|-----------------------------|-----------------------------------------------------------------------------------|------------------------------------------------------|
| 2EH        | L2_Rqsts                | Requires MESI qualification | L2 cache reference requests.                                                      | Requires core-specificity, HW prefetch qualification |
| 30H        | L2_Reject_Cycles        | Requires MESI qualification | Cycles L2 is busy and rejecting new requests.                                     |                                                      |
| 32H        | L2_No_Request_Cycles    | Requires MESI qualification | Cycles there is no request to access L2.                                          |                                                      |
| 3AH        | EST_Trans_All           | 00H                         | Any Intel Enhanced SpeedStep(R) Technology transitions.                           |                                                      |
| 3AH        | EST_Trans_All           | 10H                         | Intel Enhanced SpeedStep Technology frequency transitions.                        |                                                      |
| 3BH        | Thermal_Trip            | COH                         | Duration in a thermal trip based on the current core clock.                       | Use edge trigger to count occurrence                 |
| 3CH        | NonHlt_Ref_Cycles       | 01H                         | Non-halted bus cycles.                                                            |                                                      |
| 3CH        | Serial_Execution_Cycles | 02H                         | Non-halted bus cycles of this core executing code while the other core is halted. |                                                      |
| 40H        | DCache_Cache_LD         | Requires MESI qualification | L1 cacheable data read operations.                                                |                                                      |
| 41H        | DCache_Cache_ST         | Requires MESI qualification | L1 cacheable data write operations.                                               |                                                      |
| 42H        | DCache_Cache_Lock       | Requires MESI qualification | L1 cacheable lock read operations to invalid state.                               |                                                      |
| 43H        | Data_Mem_Ref            | 01H                         | L1 data read and writes of cacheable and non-cacheable types.                     |                                                      |
| 44H        | Data_Mem_Cache_Ref      | 02H                         | L1 data cacheable read and write operations.                                      |                                                      |
| 45H        | DCache_Repl             | 0FH                         | L1 data cache line replacements.                                                  |                                                      |
| 46H        | DCache_M_Repl           | 00H                         | L1 data M-state cache line allocated.                                             |                                                      |

## PERFORMANCE-MONITORING EVENTS

**Table A-12. Non-Architectural Performance Events  
in Intel Core Solo and Intel Core Duo Processors (Contd.)**

| Event Num. | Event Mask Mnemonic | Umask Value                                          | Description                                                                                                                                                                  | Comment                                                                                       |
|------------|---------------------|------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------|
| 47H        | DCache_M_Evict      | 00H                                                  | L1 data M-state cache line evicted.                                                                                                                                          |                                                                                               |
| 48H        | DCache_Pend_Miss    | 00H                                                  | Weighted cycles of L1 miss outstanding.                                                                                                                                      | Use Cmask =1 to count duration.                                                               |
| 49H        | Dtlb_Miss           | 00H                                                  | Data references that missed TLB.                                                                                                                                             |                                                                                               |
| 4BH        | SSE_PrefNta_Miss    | 00H                                                  | PREFETCHNTA missed all caches.                                                                                                                                               |                                                                                               |
| 4BH        | SSE_PrefT1_Miss     | 01H                                                  | PREFETCHT1 missed all caches.                                                                                                                                                |                                                                                               |
| 4BH        | SSE_PrefT2_Miss     | 02H                                                  | PREFETCHT2 missed all caches.                                                                                                                                                |                                                                                               |
| 4BH        | SSE_NTStores_Miss   | 03H                                                  | SSE streaming store instruction missed all caches.                                                                                                                           |                                                                                               |
| 4FH        | L1_Pref_Req         | 00H                                                  | L1 prefetch requests due to DCU cache misses.                                                                                                                                | May overcount if request re-submitted                                                         |
| 60H        | Bus_Req_Outstanding | 00; Requires core-specificity, and agent specificity | Weighted cycles of cacheable bus data read requests. This event counts full-line read request from DCU or HW prefetcher, but not RFO, write, instruction fetches, or others. | Use Cmask =1 to count duration.<br>Use Umask bit 12 to include HWP or exclude HWP separately. |
| 61H        | Bus_BNR_Clocks      | 00H                                                  | External bus cycles while BNR asserted.                                                                                                                                      |                                                                                               |
| 62H        | Bus_DRDY_Clocks     | 00H                                                  | External bus cycles while DRDY asserted.                                                                                                                                     | Requires agent specificity                                                                    |
| 63H        | Bus_Locks_Clocks    | 00H                                                  | External bus cycles while bus lock signal asserted.                                                                                                                          | Requires core specificity                                                                     |

**Table A-12. Non-Architectural Performance Events  
in Intel Core Solo and Intel Core Duo Processors (Contd.)**

| Event Num. | Event Mask Mnemonic | Umask Value  | Description                                                                                      | Comment                                                                        |
|------------|---------------------|--------------|--------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------|
| 66H        | Bus_Trans_RFO       | See comment. | Completed read for ownership (RFO) transactions.                                                 | Requires agent specificity                                                     |
| 68H        | Bus_Trans_Ifetch    | See comment. | Completed instruction fetch transactions.                                                        | Requires core specificity                                                      |
| 69H        | Bus_Trans_Inval     | See comment. | Completed invalidate transactions.                                                               | Each transaction counts its address strobe                                     |
| 6AH        | Bus_Trans_Pwr       | See comment. | Completed partial write transactions.                                                            | Retried transaction may be counted                                             |
| 6BH        | Bus_Trans_P         | See comment. | Completed partial transactions (include partial read + partial write + line write).              | more than once                                                                 |
| 6CH        | Bus_Trans_IO        | See comment. | Completed I/O transactions (read and write).                                                     |                                                                                |
| 6DH        | Bus_Trans_Def       | 20H          | Completed defer transactions.                                                                    | Requires core specificity<br>Retried transaction may be counted more than once |
| 67H        | Bus_Trans_WB        | COH          | Completed writeback transactions from DCU (does not include L2 writebacks).                      | Requires agent specificity                                                     |
| 6EH        | Bus_Trans_Burst     | COH          | Completed burst transactions (full line transactions include reads, write, RFO, and writebacks). | Each transaction counts its address strobe                                     |
| 6FH        | Bus_Trans_Mem       | COH          | Completed memory transactions. This includes Bus_Trans_Burst + Bus_Trans_P+Bus_Trans_Inval.      | Retried transaction may be counted                                             |
| 70H        | Bus_Trans_Any       | COH          | Any completed bus transactions.                                                                  | more than once                                                                 |
| 77H        | Bus_Snoops          | 00H          | Counts any snoop on the bus.                                                                     | Requires MESI qualification<br>Requires agent specificity                      |
| 78H        | DCU_Snoop_To_Share  | 01H          | DCU snoops to share-state L1 cache line due to L1 misses.                                        | Requires core specificity                                                      |
| 7DH        | Bus_Not_In_Use      | 00H          | Number of cycles there is no transaction from the core.                                          | Requires core specificity                                                      |

## PERFORMANCE-MONITORING EVENTS

**Table A-12. Non-Architectural Performance Events  
in Intel Core Solo and Intel Core Duo Processors (Contd.)**

| Event Num. | Event Mask Mnemonic   | Umask Value | Description                                                                                                                 | Comment |
|------------|-----------------------|-------------|-----------------------------------------------------------------------------------------------------------------------------|---------|
| 7EH        | Bus_Snoop_Stall       | 00H         | Number of bus cycles while bus snoop is stalled.                                                                            |         |
| 80H        | ICache_Reads          | 00H         | Number of instruction fetches from ICache, streaming buffers (both cacheable and uncacheable fetches).                      |         |
| 81H        | ICache_Misses         | 00H         | Number of instruction fetch misses from ICache, streaming buffers.                                                          |         |
| 85H        | ITLB_Misses           | 00H         | Number of iTLB misses.                                                                                                      |         |
| 86H        | IFU_Mem_Stall         | 00H         | Cycles IFU is stalled while waiting for data from memory.                                                                   |         |
| 87H        | ILD_Stall             | 00H         | Number of instruction length decoder stalls (Counts number of LCP stalls).                                                  |         |
| 88H        | Br_Inst_Exec          | 00H         | Branch instruction executed (includes speculation).                                                                         |         |
| 89H        | Br_Missp_Exec         | 00H         | Branch instructions executed and mispredicted at execution (includes branches that do not have prediction or mispredicted). |         |
| 8AH        | Br_BAC_Missp_Exec     | 00H         | Branch instructions executed that were mispredicted at front end.                                                           |         |
| 8BH        | Br_Cnd_Exec           | 00H         | Conditional branch instructions executed.                                                                                   |         |
| 8CH        | Br_Cnd_Missp_Exec     | 00H         | Conditional branch instructions executed that were mispredicted.                                                            |         |
| 8DH        | Br_Ind_Exec           | 00H         | Indirect branch instructions executed.                                                                                      |         |
| 8EH        | Br_Ind_Missp_Exec     | 00H         | Indirect branch instructions executed that were mispredicted.                                                               |         |
| 8FH        | Br_Ret_Exec           | 00H         | Return branch instructions executed.                                                                                        |         |
| 90H        | Br_Ret_Missp_Exec     | 00H         | Return branch instructions executed that were mispredicted.                                                                 |         |
| 91H        | Br_Ret_BAC_Missp_Exec | 00H         | Return branch instructions executed that were mispredicted at the front end.                                                |         |

**Table A-12. Non-Architectural Performance Events  
in Intel Core Solo and Intel Core Duo Processors (Contd.)**

| Event Num. | Event Mask Mnemonic | Umask Value | Description                                                                                             | Comment             |
|------------|---------------------|-------------|---------------------------------------------------------------------------------------------------------|---------------------|
| 92H        | Br_Call_Exec        | 00H         | Return call instructions executed.                                                                      |                     |
| 93H        | Br_Call_Mispp_Exec  | 00H         | Return call instructions executed that were mispredicted.                                               |                     |
| 94H        | Br_Ind_Call_Exec    | 00H         | Indirect call branch instructions executed.                                                             |                     |
| A2H        | Resource_Stall      | 00H         | Cycles while there is a resource related stall (renaming, buffer entries) as seen by allocator.         |                     |
| B0H        | MMX_Instr_Exec      | 00H         | Number of MMX instructions executed (does not include MOVQ and MOVD stores).                            |                     |
| B1H        | SIMD_Int_Sat_Exec   | 00H         | Number of SIMD Integer saturating instructions executed.                                                |                     |
| B3H        | SIMD_Int_Pmul_Exec  | 01H         | Number of SIMD Integer packed multiply instructions executed.                                           |                     |
| B3H        | SIMD_Int_Psft_Exec  | 02H         | Number of SIMD Integer packed shift instructions executed.                                              |                     |
| B3H        | SIMD_Int_Pck_Exec   | 04H         | Number of SIMD Integer pack operations instruction executed.                                            |                     |
| B3H        | SIMD_Int_Upck_Exec  | 08H         | Number of SIMD Integer unpack instructions executed.                                                    |                     |
| B3H        | SIMD_Int_Plog_Exec  | 10H         | Number of SIMD Integer packed logical instructions executed.                                            |                     |
| B3H        | SIMD_Int_Pari_Exec  | 20H         | Number of SIMD Integer packed arithmetic instructions executed.                                         |                     |
| C0H        | Instr_Ret           | 00H         | Number of instruction retired (Macro fused instruction count as 2).                                     |                     |
| C1H        | FP_Comp_Instr_Ret   | 00H         | Number of FP compute instructions retired (X87 instruction or instruction that contain X87 operations). | Use IA32_PMC0 only. |
| C2H        | Uops_Ret            | 00H         | Number of micro-ops retired (include fused uops).                                                       |                     |
| C3H        | SMC_Detected        | 00H         | Number of times self-modifying code condition detected.                                                 |                     |

## PERFORMANCE-MONITORING EVENTS

**Table A-12. Non-Architectural Performance Events  
in Intel Core Solo and Intel Core Duo Processors (Contd.)**

| Event Num. | Event Mask Mnemonic       | Umask Value | Description                                                                   | Comment |
|------------|---------------------------|-------------|-------------------------------------------------------------------------------|---------|
| C4H        | Br_Instr_Ret              | 00H         | Number of branch instructions retired.                                        |         |
| C5H        | Br_MisPred_Ret            | 00H         | Number of mispredicted branch instructions retired.                           |         |
| C6H        | Cycles_Int_Masked         | 00H         | Cycles while interrupt is disabled.                                           |         |
| C7H        | Cycles_Int_Pending_Masked | 00H         | Cycles while interrupt is disabled and interrupts are pending.                |         |
| C8H        | HW_Int_Rx                 | 00H         | Number of hardware interrupts received.                                       |         |
| C9H        | Br_Taken_Ret              | 00H         | Number of taken branch instruction retired.                                   |         |
| CAH        | Br_MisPred_Taken_Ret      | 00H         | Number of taken and mispredicted branch instructions retired.                 |         |
| CCH        | MMX_FP_Trans              | 00H         | Number of transitions from MMX to X87.                                        |         |
| CCH        | FP_MMX_Trans              | 01H         | Number of transitions from X87 to MMX.                                        |         |
| CDH        | MMX_Assist                | 00H         | Number of EMMS executed.                                                      |         |
| CEH        | MMX_Instr_Ret             | 00H         | Number of MMX instruction retired.                                            |         |
| DOH        | Instr_Decoded             | 00H         | Number of instruction decoded.                                                |         |
| D7H        | ESP_Uops                  | 00H         | Number of ESP folding instruction decoded.                                    |         |
| D8H        | SIMD_FP_SP_Ret            | 00H         | Number of SSE/SSE2 single precision instructions retired (packed and scalar). |         |
| D8H        | SIMD_FP_SP_S_Ret          | 01H         | Number of SSE/SSE2 scalar single precision instructions retired.              |         |
| D8H        | SIMD_FP_DP_P_Ret          | 02H         | Number of SSE/SSE2 packed double precision instructions retired.              |         |
| D8H        | SIMD_FP_DP_S_Ret          | 03H         | Number of SSE/SSE2 scalar double precision instructions retired.              |         |
| D8H        | SIMD_Int_128_Ret          | 04H         | Number of SSE2 128 bit integer instructions retired.                          |         |

**Table A-12. Non-Architectural Performance Events  
in Intel Core Solo and Intel Core Duo Processors (Contd.)**

| Event Num. | Event Mask Mnemonic   | Umask Value | Description                                                                                              | Comment |
|------------|-----------------------|-------------|----------------------------------------------------------------------------------------------------------|---------|
| D9H        | SIMD_FP_SP_P_Comp_Ret | 00H         | Number of SSE/SSE2 packed single precision compute instructions retired (does not include AND, OR, XOR). |         |
| D9H        | SIMD_FP_SP_S_Comp_Ret | 01H         | Number of SSE/SSE2 scalar single precision compute instructions retired (does not include AND, OR, XOR). |         |
| D9H        | SIMD_FP_DP_P_Comp_Ret | 02H         | Number of SSE/SSE2 packed double precision compute instructions retired (does not include AND, OR, XOR). |         |
| D9H        | SIMD_FP_DP_S_Comp_Ret | 03H         | Number of SSE/SSE2 scalar double precision compute instructions retired (does not include AND, OR, XOR). |         |
| DAH        | Fused_Uops_Ret        | 00H         | All fused uops retired.                                                                                  |         |
| DAH        | Fused_Ld_Uops_Ret     | 01H         | Fused load uops retired.                                                                                 |         |
| DAH        | Fused_St_Uops_Ret     | 02H         | Fused store uops retired.                                                                                |         |
| DBH        | Unfusion              | 00H         | Number of unfusion events in the ROB (due to exception).                                                 |         |
| EOH        | Br_Instr_Decoded      | 00H         | Branch instructions decoded.                                                                             |         |
| E2H        | BTB_Misses            | 00H         | Number of branches the BTB did not produce a prediction.                                                 |         |
| E4H        | Br_Bogus              | 00H         | Number of bogus branches.                                                                                |         |
| E6H        | BAClears              | 00H         | Number of BAClears asserted.                                                                             |         |
| F0H        | Pref_Rqsts_Up         | 00H         | Number of hardware prefetch requests issued in forward streams.                                          |         |
| F8H        | Pref_Rqsts_Dn         | 00H         | Number of hardware prefetch requests issued in backward streams.                                         |         |

## A.9 PENTIUM 4 AND INTEL XEON PROCESSOR PERFORMANCE-MONITORING EVENTS

Tables A-13, A-14 and A-15 list performance-monitoring events that can be counted or sampled on processors based on Intel NetBurst® microarchitecture. Table A-13 lists the non-retirement events, and Table A-14 lists the at-retirement events. Tables A-16, A-17, and A-18 describes three sets of parameters that are available for three of the at-retirement counting events defined in Table A-14. Table A-19 shows which of the non-retirement and at retirement events are logical processor specific (TS) (see Section 30.10.4, "Performance Monitoring Events") and which are non-logical processor specific (TI).

Some of the Pentium 4 and Intel Xeon processor performance-monitoring events may be available only to specific models. The performance-monitoring events listed in Tables A-13 and A-14 apply to processors with CPUID signature that matches family encoding 15, model encoding 0, 1, 2, 3, 4, or 6. Table A-15 applies to processors with a CPUID signature that matches family encoding 15, model encoding 3, 4 or 6.

The functionality of performance-monitoring events in Pentium 4 and Intel Xeon processors is also available when IA-32e mode is enabled.

**Table A-13. Performance Monitoring Events Supported by Intel NetBurst Microarchitecture for Non-Retirement Counting**

| Event Name      | Event Parameters         | Parameter Value              | Description                                                                                                                                                                                         |
|-----------------|--------------------------|------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| TC_deliver_mode |                          |                              | This event counts the duration (in clock cycles) of the operating modes of the trace cache and decode engine in the processor package. The mode is specified by one or more of the event mask bits. |
|                 | ESCR restrictions        | MSR_TC_ESCRO<br>MSR_TC_ESCR1 |                                                                                                                                                                                                     |
|                 | Counter numbers per ESCR | ESCRO: 4, 5<br>ESCR1: 6, 7   |                                                                                                                                                                                                     |

|            | Event Specific Notes     |                                                                                                                       | 1: The implementation of this event in current Pentium 4 and Xeon processors treats either a load operation or a request for ownership (RFO) request as a "read" type operation.                                                                                                                                                                                                           |

## PERFORMANCE-MONITORING EVENTS

**Table A-13. Performance Monitoring Events Supported by Intel NetBurst Microarchitecture for Non-Retirement Counting (Contd.)**

| Event Name     | Event Parameters | Parameter Value | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|----------------|------------------|-----------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                |                  |                 | <p>2: Currently this event causes both over and undercounting by as much as a factor of two due to an erratum.</p> <p>3: It is possible for a transaction that is started as a prefetch to change the transaction's internal status, making it no longer a prefetch. or change the access result status (hit, miss) as seen by this event.</p>                                                                                                                                                                                                 |
| IOQ_allocation |                  |                 | <p>This event counts the various types of transactions on the bus. A count is generated each time a transaction is allocated into the IOQ that matches the specified mask bits. An allocated entry can be a sector (64 bytes) or a chunks of 8 bytes.</p>                                                                                                                                                                                                                                                                                      |
|                |                  |                 | <p>Requests are counted once per retry. The event mask bits constitute 4 bit fields. A transaction type is specified by interpreting the values of each bit field.</p> <p>Specify one or more event mask bits in a bit field to select the value of the bit field.</p> <p>Each field (bits 0-4 are one field) are independent of and can be ORed with the others. The request type field is further combined with bit 5 and 6 to form a binary expression. Bits 7 and 8 form a bit field to specify the memory type of the target address.</p> |

## PERFORMANCE-MONITORING EVENTS

**Table A-13. Performance Monitoring Events Supported by Intel NetBurst Microarchitecture for Non-Retirement Counting (Contd.)**

| Event Name | Event Parameters     | Parameter Value | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|------------|----------------------|-----------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|            | Event Specific Notes |                 | <p>1: If PREFETCH bit is cleared, sectors fetched using prefetch are excluded in the counts. If PREFETCH bit is set, all sectors or chunks read are counted.</p> <p>2: Specify the edge trigger in CCCR to avoid double counting.</p> <p>3: The mapping of interpreted bit field values to transaction types may differ with different processor model implementations of the Pentium 4 processor family. Applications that program performance monitoring events should use CPUID to determine processor models when using this event. The logic equations that trigger the event are model-specific (see 4a and 4b below).</p> <p>4a: For Pentium 4 and Xeon Processors starting with CPUID Model field encoding equal to 2 or greater, this event is triggered by evaluating the logical expression ((Request type) and (Bit 5 or Bit 6) and (Memory type) and (Source agent)).</p> |

## PERFORMANCE-MONITORING EVENTS

**Table A-13. Performance Monitoring Events Supported by Intel NetBurst Microarchitecture for Non-Retirement Counting (Contd.)**

| Event Name | Event Parameters | Parameter Value | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|------------|------------------|-----------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|            |                  |                 | <p>4b: For Pentium 4 and Xeon Processors with CPUID Model field encoding less than 2, this event is triggered by evaluating the logical expression [(Request type) or Bit 5 or Bit 6] or (Memory type)] and (Source agent). Note that event mask bits for memory type are ignored if either ALL_READ or ALL_WRITE is specified.</p> <p>5: This event is known to ignore CPL in early implementations of Pentium 4 and Xeon Processors. Both user requests and OS requests are included in the count. This behavior is fixed starting with Pentium 4 and Xeon Processors with CPUID signature 0xF27 (Family 15, Model 2, Stepping 7).</p> <p>6: For write-through (WT) and write-protected (WP) memory types, this event counts reads as the number of 64-byte sectors. Writes are counted by individual chunks.</p> <p>7: For uncacheable (UC) memory types, this event counts the number of 8-byte chunks allocated.</p> <p>8: For Pentium 4 and Xeon Processors with CPUID Signature less than 0xF27, only MSR_FSB_ESCRO is available.</p> |

## PERFORMANCE-MONITORING EVENTS

## PERFORMANCE-MONITORING EVENTS

**Table A-13. Performance Monitoring Events Supported by Intel NetBurst Microarchitecture for Non-Retirement Counting (Contd.)**

| Event Name       | Event Parameters | Parameter Value | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|------------------|------------------|-----------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                  |                  |                 | <p>4: This event can be used to estimate the latency of a transaction from allocation to de-allocation in the BSQ. The latency observed by BSQ_allocation includes the latency of FSB, plus additional overhead.</p> <p>5: Additional overhead may include the time it takes to issue two requests (the sector by demand and the adjacent sector via prefetch). Since adjacent sector prefetches have lower priority than demand fetches, on a heavily used system there is a high probability that the adjacent sector prefetch will have to wait until the next bus arbitration.</p> <p>6: For Pentium 4 and Xeon processors with CPUID model encoding value less than 3, this event is updated every clock.</p> <p>7: For Pentium 4 and Xeon processors with CPUID model encoding value equals to 3 or 4, this event is updated every other clock.</p> |
| SSE_input_assist |                  |                 | This event counts the number of times an assist is requested to handle problems with input operands for SSE/SSE2/SSE3 operations; most notably denormal source operands when the DAZ bit is not set. Set bit 15 of the event mask to use this event.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

**Table A-13. Performance Monitoring Events Supported by Intel NetBurst Microarchitecture for Non-Retirement Counting (Contd.)**

|            | CCCR Select              | 01H                              | CCCR[15:13]                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|            | Event Specific Notes     |                                  | 1: Not all requests for assists are actually taken. This event is known to overcount in that it counts requests for assists from instructions on the non-retired path that do not incur a performance penalty. An assist is actually taken only for non-bogus $\mu$ ops. Any appreciable counts for this event are an indication that the DAZ or FTZ bit should be set and/or the source code should be changed to eliminate the condition. |
|            |                          |                                  | 2: Two common situations for an SSE/SSE2/SSE3 operation needing an assist are: (1) when a denormal constant is used as an input and the Denormals-Are-Zero (DAZ) mode is not set, (2) when the input operand uses the underflowed result of a previous SSE/SSE2/SSE3 operation and neither the DAZ nor Flush-To-Zero (FTZ) modes are set.                                                                                                   |

|                 | Can Support PEBS         | No                                     |                                                                                                                                                                            |

## PERFORMANCE-MONITORING EVENTS

**Table A-16. List of Metrics Available for Front\_end Tagging  
(For Front\_end Event Only)**

| Front-end metric <sup>1</sup> | MSR_TC_PRECISE_EVENT MSR Bit field | Additional MSR                                                 | Event mask value for Front_end_event |
|-------------------------------|------------------------------------|----------------------------------------------------------------|--------------------------------------|
| memory_loads                  | None                               | Set TAGLOADS bit in ESCR corresponding to event Uop_Type.      | NBOGUS                               |
| memory_stores                 | None                               | Set TAGSTORES bit in the ESCR corresponding to event Uop_Type. | NBOGUS                               |

**NOTES:**

1. There may be some undercounting of front end events when there is an overflow or underflow of the floating point stack.

**Table A-17. List of Metrics Available for Execution Tagging  
(For Execution Event Only)**

| Execution metric    | Upstream ESCR                                                     | TagValue in Upstream ESCR | Event mask value for execution_event |
|---------------------|-------------------------------------------------------------------|---------------------------|--------------------------------------|
| packed_SP_retired   | Set ALL bit in event mask, TagUop bit in ESCR of packed_SP_uop.   | 1                         | NBOGUS0                              |
| packed_DP_retired   | Set ALL bit in event mask, TagUop bit in ESCR of packed_DP_uop.   | 1                         | NBOGUS0                              |
| scalar_SP_retired   | Set ALL bit in event mask, TagUop bit in ESCR of scalar_SP_uop.   | 1                         | NBOGUS0                              |
| scalar_DP_retired   | Set ALL bit in event mask, TagUop bit in ESCR of scalar_DP_uop.   | 1                         | NBOGUS0                              |
| 128_bit_MMX_retired | Set ALL bit in event mask, TagUop bit in ESCR of 128_bit_MMX_uop. | 1                         | NBOGUS0                              |

**Table A-17. List of Metrics Available for Execution Tagging  
(For Execution Event Only) (Contd.)**

| Execution metric              | Upstream ESCR                                                                  | TagValue in Upstream ESCR | Event mask value for execution_event |
|-------------------------------|--------------------------------------------------------------------------------|---------------------------|--------------------------------------|
| 64_bit_MMX_retired            | Set ALL bit in event mask, TagUop bit in ESCR of 64_bit_MMX_uop.               | 1                         | NBOGUSO                              |
| X87_FP_retired                | Set ALL bit in event mask, TagUop bit in ESCR of x87_FP_uop.                   | 1                         | NBOGUSO                              |
| X87 SIMD memory moves_retired | Set ALLPO, ALLP2 bits in event mask, TagUop bit in ESCR of X87 SIMD moves_uop. | 1                         | NBOGUSO                              |

**Table A-18. List of Metrics Available for Replay Tagging  
(For Replay Event Only)**

| Replay metric <sup>1</sup>                | IA32_PEBS_ENABLE Field to Set  | MSR_PEBS_MATRIX_VERT Bit Field to Set | Additional MSR/Event                                                   | Event Mask Value for Replay_event |
|-------------------------------------------|--------------------------------|---------------------------------------|------------------------------------------------------------------------|-----------------------------------|

## PERFORMANCE-MONITORING EVENTS

**Table A-18. List of Metrics Available for Replay Tagging  
(For Replay Event Only) (Contd.)**

| Replay metric <sup>1</sup> | IA32_PEBS_ENABLE Field to Set | MSR_PEBS_MATRIX_VERT Bit Field to Set | Additional MSR/Event                                                                      | Event Mask Value for Replay_event |
|----------------------------|-------------------------------|---------------------------------------|-------------------------------------------------------------------------------------------|-----------------------------------|
| split_load_retired         | Bit 10, Bit 24, Bit 25        | Bit 0                                 | Select load_port_replay event with the MSR_SAAT_ESCR1 MSR and set the SPLIT_LD mask bit.  | NBOGUS                            |
| split_store_retired        | Bit 10, Bit 24, Bit 25        | Bit 1                                 | Select store_port_replay event with the MSR_SAAT_ESCRO MSR and set the SPLIT_ST mask bit. | NBOGUS                            |

**NOTES:**

1. Certain kinds of  $\mu$ ops cannot be tagged. These include I/O operations, UC and locked accesses, returns, and far transfers.
2. 2nd-level misses retired does not count all 2nd-level misses. It only includes those references that are found to be misses by the fast detection logic and not those that are later found to be misses.
3. While there are several causes for a MOB replay, the event counted with this event mask setting is the case where the data from a load that would otherwise be forwarded is not an aligned subset of the data from a preceding store.

## A.10 PERFORMANCE MONITORING EVENTS FOR INTEL® PENTIUM® M PROCESSORS

The Pentium M processor's performance-monitoring events are based on monitoring events for the P6 family of processors. All of these performance events are model specific for the Pentium M processor and are not available in this form in other processors. Table A-20 lists the Performance-Monitoring events that were added in the Pentium M processor.

**Table A-20. Performance Monitoring Events on Intel® Pentium® M Processors**

| Name              | Hex Values | Descriptions                                                                                                                           |
|-------------------|------------|----------------------------------------------------------------------------------------------------------------------------------------|
| Power Management  |            |                                                                                                                                        |
| EMON_EST_TRANS    | 58H        | Number of Enhanced Intel SpeedStep technology transitions:<br>Mask = 00H - All transitions<br>Mask = 02H - Only Frequency transitions  |
| EMON_THERMAL_TRIP | 59H        | Duration/Occurrences in thermal trip; to count number of thermal trips: bit 22 in PerfEvtSel0/1 needs to be set to enable edge detect. |
| BPU               |            |                                                                                                                                        |
| BR_INST_EXEC      | 88H        | Branch instructions that were executed (not necessarily retired).                                                                      |
| BR_MISSP_EXEC     | 89H        | Branch instructions executed that were mispredicted at execution.                                                                      |

## PERFORMANCE-MONITORING EVENTS

**Table A-20. Performance Monitoring Events on Intel® Pentium® M Processors (Contd.)**

| Name                    | Hex Values | Descriptions                                                                                                                               |
|-------------------------|------------|--------------------------------------------------------------------------------------------------------------------------------------------|
| BR_BAC_MISSP_EXEC       | 8AH        | Branch instructions executed that were mispredicted at front end (BAC).                                                                    |
| BR_CND_EXEC             | 8BH        | Conditional branch instructions that were executed.                                                                                        |
| BR_CND_MISSP_EXEC       | 8CH        | Conditional branch instructions executed that were mispredicted.                                                                           |
| BR_IND_EXEC             | 8DH        | Indirect branch instructions executed.                                                                                                     |
| BR_IND_MISSP_EXEC       | 8EH        | Indirect branch instructions executed that were mispredicted.                                                                              |
| BR_RET_EXEC             | 8FH        | Return branch instructions executed.                                                                                                       |
| BR_RET_MISSP_EXEC       | 90H        | Return branch instructions executed that were mispredicted at execution.                                                                   |
| BR_RET_BAC_MISSP_EXEC   | 91H        | Return branch instructions executed that were mispredicted at front end (BAC).                                                             |
| BR_CALL_EXEC            | 92H        | CALL instruction executed.                                                                                                                 |
| BR_CALL_MISSP_EXEC      | 93H        | CALL instruction executed and miss predicted.                                                                                              |
| BR_IND_CALL_EXEC        | 94H        | Indirect CALL instructions executed.                                                                                                       |
| Decoder                 |            |                                                                                                                                            |
| EMON SIMD_INSTR_RETIRED | CEH        | Number of retired MMX instructions.                                                                                                        |
| EMON_SYNCH_UOPS         | D3H        | Sync micro-ops                                                                                                                             |
| EMON_ESP_UOPS           | D7H        | Total number of micro-ops                                                                                                                  |
| EMON_FUSED_UOPS_RET     | DAH        | Number of retired fused micro-ops:<br>Mask = 0 - Fused micro-ops<br>Mask = 1 - Only load+Op micro-ops<br>Mask = 2 - Only std+sta micro-ops |
| EMON_UNFUSION           | DBH        | Number of unfusion events in the ROB, happened on a FP exception to a fused $\mu$ op.                                                      |

**Table A-20. Performance Monitoring Events on Intel® Pentium® M Processors (Contd.)**

| Name               | Hex Values | Descriptions                         |
|--------------------|------------|--------------------------------------|
| Prefetcher         |            |                                      |
| EMON_PREF_RQSTS_UP | F0H        | Number of upward prefetches issued   |
| EMON_PREF_RQSTS_DN | F8H        | Number of downward prefetches issued |

A number of P6 family processor performance monitoring events are modified for the Pentium M processor. Table A-21 lists the performance monitoring events that were changed in the Pentium M processor, and differ from performance monitoring events for the P6 family of processors.

**Table A-21. Performance Monitoring Events Modified on Intel® Pentium® M Processors**

| Name                            | Hex Values | Descriptions                                                                                                                                                                                        |
|---------------------------------|------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| CPU_CLK_UNHALTED                | 79H        | Number of cycles during which the processor is not halted, and not in a thermal trip.                                                                                                               |

## A.11 P6 FAMILY PROCESSOR PERFORMANCE-MONITORING EVENTS

Table A-22 lists the events that can be counted with the performance-monitoring counters and read with the RDPMC instruction for the P6 family processors. The unit column gives the microarchitecture or bus unit that produces the event; the event number column gives the hexadecimal number identifying the event; the mnemonic event name column gives the name of the event; the unit mask column gives the unit mask required (if any); the description column describes the event; and the comments column gives additional information about the event.

All of these performance events are model specific for the P6 family processors and are not available in this form in the Pentium 4 processors or the Pentium processors. Some events (such as those added in later generations of the P6 family processors) are only available in specific processors in the P6 family. All performance event encodings not listed in Table A-22 are reserved and their use will result in undefined counter results.

See the end of the table for notes related to certain entries in the table.

**Table A-22. Events That Can Be Counted with the P6 Family Performance-Monitoring Counters**

| Unit                  | Event Num. | Mnemonic Event Name | Unit Mask | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    | Comments |
|-----------------------|------------|---------------------|-----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------|
| Data Cache Unit (DCU) | 43H        | DATA_MEM_REFs       | 00H       | <p>All loads from any memory type. All stores to any memory type. Each part of a split is counted separately. The internal logic counts not only memory loads and stores, but also internal retries.</p> <p>80-bit floating-point accesses are double counted, since they are decomposed into a 16-bit exponent load and a 64-bit mantissa load.</p> <p>Memory accesses are only counted when they are actually performed (such as a load that gets squashed because a previous cache miss is outstanding to the same address, and which finally gets performed, is only counted once).</p> <p>Does not include I/O accesses, or other nonmemory accesses.</p> |          |
|                       | 45H        | DCU_LINES_IN        | 00H       | Total lines allocated in DCU.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |          |
|                       | 46H        | DCU_M_LINES_IN      | 00H       | Number of M state lines allocated in DCU.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |          |
|                       | 47H        | DCU_M_LINES_OUT     | 00H       | <p>Number of M state lines evicted from DCU.</p> <p>This includes evictions via snoop HITM, intervention or replacement.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |          |

## PERFORMANCE-MONITORING EVENTS

**Table A-22. Events That Can Be Counted with the P6 Family Performance-Monitoring Counters (Contd.)**

| Unit                         | Event Num. | Mnemonic Event Name  | Unit Mask | Description                                                                                                                                                                                                                                                                                                        | Comments                                                                                                                                                                                                                                            |
|------------------------------|------------|----------------------|-----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                              | 48H        | DCU_MISS_OUTSTANDING | 00H       | Weighted number of cycles while a DCU miss is outstanding, incremented by the number of outstanding cache misses at any particular time.<br>Cacheable read requests only are considered.<br>Uncacheable requests are excluded.<br>Read-for-ownerships are counted, as well as line fills, invalidates, and stores. | An access that also misses the L2 is short-changed by 2 cycles (i.e., if counts N cycles, should be N+2 cycles).<br>Subsequent loads to the same cache line will not result in any additional counts.<br>Count value not precise, but still useful. |
| Instruction Fetch Unit (IFU) | 80H        | IFU_IFETCH           | 00H       | Number of instruction fetches, both cacheable and noncacheable, including UC fetches.                                                                                                                                                                                                                              |                                                                                                                                                                                                                                                     |
|                              | 81H        | IFU_IFETCH_MISS      | 00H       | Number of instruction fetch misses<br>All instruction fetches that do not hit the IFU (i.e., that produce memory requests). This includes UC accesses.                                                                                                                                                             |                                                                                                                                                                                                                                                     |
|                              | 85H        | ITLB_MISS            | 00H       | Number of ITLB misses.                                                                                                                                                                                                                                                                                             |                                                                                                                                                                                                                                                     |

## PERFORMANCE-MONITORING EVENTS

**Table A-22. Events That Can Be Counted with the P6 Family Performance-Monitoring Counters (Contd.)**

| Unit | Event Num. | Mnemonic Event Name | Unit Mask | Description                                                                                                                                                                                                                                                                                                                                              | Comments |
|------|------------|---------------------|-----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------|
|      |            |                     |           | it indicates that the DCU sent a read-for-ownership request to the L2. It also includes Invalid to Modified requests sent by the DCU to the L2.<br>It includes only L2 cacheable memory accesses; it does not include I/O accesses, other nonmemory accesses, or memory accesses such as UC/WT memory accesses.<br>It includes TLB miss memory accesses. |          |
|      | 24H        | L2_LINES_IN         | 00H       | Number of lines allocated in the L2.                                                                                                                                                                                                                                                                                                                     |          |
|      | 26H        | L2_LINES_OUT        | 00H       | Number of lines removed from the L2 for any reason.                                                                                                                                                                                                                                                                                                      |          |
|      | 25H        | L2_M_LINES_INM      | 00H       | Number of modified lines allocated in the L2.                                                                                                                                                                                                                                                                                                            |          |
|      | 27H        | L2_M_LINES_OUTM     | 00H       | Number of modified lines removed from the L2 for any reason.                                                                                                                                                                                                                                                                                             |          |
|      | 2EH        | L2_RQSTS            | MESI OFH  | Total number of L2 requests.                                                                                                                                                                                                                                                                                                                             |          |
|      | 21H        | L2_ADS              | 00H       | Number of L2 address strobes.                                                                                                                                                                                                                                                                                                                            |          |
|      | 22H        | L2_DBUS_BUSY        | 00H       | Number of cycles during which the L2 cache data bus was busy.                                                                                                                                                                                                                                                                                            |          |
|      | 23H        | L2_DBUS_BUSY_RD     | 00H       | Number of cycles during which the data bus was busy transferring read data from L2 to the processor.                                                                                                                                                                                                                                                     |          |

**Table A-22. Events That Can Be Counted with the P6 Family Performance-Monitoring Counters (Contd.)**

| Unit                                  | Event Num. | Mnemonic Event Name | Unit Mask               | Description                                                                                                                                  | Comments                                                                                                                                                             |
|---------------------------------------|------------|---------------------|-------------------------|----------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| External Bus Logic (EBL) <sup>2</sup> | 62H        | BUS_DRDY_CLOCKS     | 00H (Self)<br>20H (Any) | Number of clocks during which DRDY# is asserted. Utilization of the external system data bus during data transfers.                          | Unit Mask = 00H counts bus clocks when the processor is driving DRDY#. Unit Mask = 20H counts in processor clocks when any agent is driving DRDY#.                   |
|                                       | 63H        | BUS_LOCK_CLOCKS     | 00H (Self)<br>20H (Any) | Number of clocks during which LOCK# is asserted on the external system bus. <sup>3</sup>                                                     | Always counts in processor clocks.                                                                                                                                   |
|                                       | 60H        | BUS_REQ_OUTSTANDING | 00H (Self)              | Number of bus requests outstanding. This counter is incremented by the number of cacheable read bus requests outstanding in any given cycle. | Counts only DCU full-line cacheable reads, not RFOs, writes, instruction fetches, or anything else. Counts "waiting for bus to complete" (last data chunk received). |
|                                       | 65H        | BUS_TRAN_BRD        | 00H (Self)<br>20H (Any) | Number of burst read transactions.                                                                                                           |                                                                                                                                                                      |
|                                       | 66H        | BUS_TRAN_RFO        | 00H (Self)<br>20H (Any) | Number of completed read for ownership transactions.                                                                                         |                                                                                                                                                                      |
|                                       | 67H        | BUS_TRANS_WB        | 00H (Self)<br>20H (Any) | Number of completed write back transactions.                                                                                                 |                                                                                                                                                                      |

## PERFORMANCE-MONITORING EVENTS

|                                 |            |                     |                                     | Segment register FS                                      |                                                          |  |                                     |  |
|                                 |            |                     |                                     | Segment registers ES + DS + FS + GS                      |                                                          |  |                                     |  |
| 01H<br>02H<br>04H<br>08H<br>0FH |            |                     | Number of Segment Register Renames: | Available in Pentium II and Pentium III processors only. |                                                          |  |                                     |  |
|                                 |            |                     | Segment register ES                 |                                                          |                                                          |  |                                     |  |
|                                 |            |                     | D6H                                 |                                                          |                                                          |  | Segment register DS                 |  |
|                                 |            |                     |                                     |                                                          |                                                          |  | Segment register FS                 |  |
|                                 |            |                     |                                     |                                                          |                                                          |  | Segment registers ES + DS + FS + GS |  |
| D6H                             |            | RET_SEG_RENAMES     | 00H                                 | Number of segment register rename events retired.        | Available in Pentium II and Pentium III processors only. |  |                                     |  |

**NOTES:**

1. Several L2 cache events, where noted, can be further qualified using the Unit Mask (UMSK) field in the PerfEvtSel0 and PerfEvtSel1 registers. The lower 4 bits of the Unit Mask field are used in conjunction with L2 events to indicate the cache state or cache states involved. The P6 family processors identify cache states using the "MESI" protocol and consequently each bit in the Unit Mask field represents one of the four states: UMSK[3] = M (8H) state, UMSK[2] = E (4H) state, UMSK[1] = S (2H) state, and UMSK[0] = I (1H) state. UMSK[3:0] = MESI" (FH) should be used to collect data for all states; UMSK = OH, for the applicable events, will result in nothing being counted.
2. All of the external bus logic (EBL) events, except where noted, can be further qualified using the Unit Mask (UMSK) field in the PerfEvtSel0 and PerfEvtSel1 registers. Bit 5 of the UMSK field is used in conjunction with the EBL events to indicate whether the processor should count transactions that are self-generated (UMSK[5] = 0) or transactions that result from any processor on the bus (UMSK[5] = 1).
3. L2 cache locks, so it is possible to have a zero count.

## A.12 PENTIUM PROCESSOR PERFORMANCE-MONITORING EVENTS

Table A-23 lists the events that can be counted with the performance-monitoring counters for the Pentium processor. The Event Number column gives the hexadecimal code that identifies the event and that is entered in the E0 or E1 (event select) fields of the CESR MSR. The Mnemonic Event Name column gives the name of the event, and the Description and Comments columns give detailed descriptions of the events. Most events can be counted with either counter 0 or counter 1; however, some events can only be counted with only counter 0 or only counter 1 (as noted).

### NOTE

The events in the table that are shaded are implemented only in the Pentium processor with MMX technology.

**Table A-23. Events That Can Be Counted with Pentium Processor Performance-Monitoring Counters**

| Event Num. | Mnemonic Event Name | Description                                                                                 | Comments                                                                                                                                                                                        |
|------------|---------------------|---------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 00H        | DATA_READ           | Number of memory data reads (internal data cache hit and miss combined).                    | Split cycle reads are counted individually. Data Memory Reads that are part of TLB miss processing are not included. These events may occur at a maximum of two per clock. I/O is not included. |
| 01H        | DATA_WRITE          | Number of memory data writes (internal data cache hit and miss combined); I/O not included. | Split cycle writes are counted individually. These events may occur at a maximum of two per clock. I/O is not included.                                                                         |
| 0H2        | DATA_TLB_MISS       | Number of misses to the data cache translation look-aside buffer.                           |                                                                                                                                                                                                 |

**Table A-23. Events That Can Be Counted with Pentium Processor Performance-Monitoring Counters (Contd.)**

| Event Num. | Mnemonic Event Name             | Description                                                                                                               | Comments                                                                                                                                                                                                                                                                                                                                           |
|------------|---------------------------------|---------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 03H        | DATA_READ_MISS                  | Number of memory read accesses that miss the internal data cache whether or not the access is cacheable or noncacheable.  | Additional reads to the same cache line after the first BRDY# of the burst line fill is returned but before the final (fourth) BRDY# has been returned, will not cause the counter to be incremented additional times.<br>Data accesses that are part of TLB miss processing are not included.<br>Accesses directed to I/O space are not included. |
| 04H        | DATA WRITE MISS                 | Number of memory write accesses that miss the internal data cache whether or not the access is cacheable or noncacheable. | Data accesses that are part of TLB miss processing are not included.<br>Accesses directed to I/O space are not included.                                                                                                                                                                                                                           |
| 05H        | WRITE_HIT_TO_M_OR_E-STATE_LINES | Number of write hits to exclusive or modified lines in the data cache.                                                    | These are the writes that may be held up if EWBE# is inactive. These events may occur a maximum of two per clock.                                                                                                                                                                                                                                  |
| 06H        | DATA_CACHE_LINES_WRITTEN_BACK   | Number of dirty lines (all) that are written back, regardless of the cause.                                               | Replacements and internal and external snoops can all cause writeback and are counted.                                                                                                                                                                                                                                                             |
| 07H        | EXTERNAL_SNOOPS                 | Number of accepted external snoops whether they hit in the code cache or data cache or neither.                           | Assertions of EADS# outside of the sampling interval are not counted, and no internal snoops are counted.                                                                                                                                                                                                                                          |
| 08H        | EXTERNAL_DATA_CACHE_SNOOP_HITS  | Number of external snoops to the data cache.                                                                              | Snoop hits to a valid line in either the data cache, the data line fill buffer, or one of the write back buffers are all counted as hits.                                                                                                                                                                                                          |
| 09H        | MEMORY ACCESSES IN BOTH PIPES   | Number of data memory reads or writes that are paired in both pipes of the pipeline.                                      | These accesses are not necessarily run in parallel due to cache misses, bank conflicts, etc.                                                                                                                                                                                                                                                       |
| 0AH        | BANK CONFLICTS                  | Number of actual bank conflicts.                                                                                          |                                                                                                                                                                                                                                                                                                                                                    |

## PERFORMANCE-MONITORING EVENTS

**Table A-23. Events That Can Be Counted with Pentium Processor Performance-Monitoring Counters (Contd.)**

| Event Num. | Mnemonic Event Name                      | Description                                                                                                   | Comments                                                                                                                                                                                                                                                                                 |
|------------|------------------------------------------|---------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0BH        | MISALIGNED DATA MEMORY OR I/O REFERENCES | Number of memory or I/O reads or writes that are misaligned.                                                  | A 2- or 4-byte access is misaligned when it crosses a 4-byte boundary; an 8-byte access is misaligned when it crosses an 8-byte boundary. Ten byte accesses are treated as two separate accesses of 8 and 2 bytes each.                                                                  |
| OCH        | CODE READ                                | Number of instruction reads; whether the read is cacheable or noncacheable.                                   | Individual 8-byte noncacheable instruction reads are counted.                                                                                                                                                                                                                            |
| ODH        | CODE TLB MISS                            | Number of instruction reads that miss the code TLB whether the read is cacheable or noncacheable.             | Individual 8-byte noncacheable instruction reads are counted.                                                                                                                                                                                                                            |
| OEH        | CODE CACHE MISS                          | Number of instruction reads that miss the internal code cache; whether the read is cacheable or noncacheable. | Individual 8-byte noncacheable instruction reads are counted.                                                                                                                                                                                                                            |
| OFH        | ANY SEGMENT REGISTER LOADED              | Number of writes into any segment register in real or protected mode including the LDTR, GDTR, IDTR, and TR.  | Segment loads are caused by explicit segment register load instructions, far control transfers, and task switches. Far control transfers and task switches causing a privilege level change will signal this event twice. Interrupts and exceptions may initiate a far control transfer. |
| 10H        | Reserved                                 |                                                                                                               |                                                                                                                                                                                                                                                                                          |
| 11H        | Reserved                                 |                                                                                                               |                                                                                                                                                                                                                                                                                          |

**Table A-23. Events That Can Be Counted with Pentium Processor Performance-Monitoring Counters (Contd.)**

| Event Num. | Mnemonic Event Name     | Description                                                                                                                                                                          | Comments                                                                                                                                                                                                                                                                                                                                                                 |
|------------|-------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 12H        | Branches                | Number of taken and not taken branches, including: conditional branches, jumps, calls, returns, software interrupts, and interrupt returns.                                          | Also counted as taken branches are serializing instructions, VERR and VERW instructions, some segment descriptor loads, hardware interrupts (including FLUSH#), and programmatic exceptions that invoke a trap or fault handler. The pipe is not necessarily flushed.<br><br>The number of branches actually executed is measured, not the number of predicted branches. |
| 13H        | BTB_HITS                | Number of BTB hits that occur.                                                                                                                                                       | Hits are counted only for those instructions that are actually executed.                                                                                                                                                                                                                                                                                                 |
| 14H        | TAKEN_BRANCH_OR_BTB_HIT | Number of taken branches or BTB hits that occur.                                                                                                                                     | This event type is a logical OR of taken branches and BTB hits. It represents an event that may cause a hit in the BTB. Specifically, it is either a candidate for a space in the BTB or it is already in the BTB.                                                                                                                                                       |
| 15H        | PIPELINE_FLUSHES        | Number of pipeline flushes that occur<br><br>Pipeline flushes are caused by BTB misses on taken branches, mispredictions, exceptions, interrupts, and some segment descriptor loads. | The counter will not be incremented for serializing instructions (serializing instructions cause the prefetch queue to be flushed but will not trigger the Pipeline Flushed event counter) and software interrupts (software interrupts do not flush the pipeline).                                                                                                      |

## PERFORMANCE-MONITORING EVENTS

**Table A-23. Events That Can Be Counted with Pentium Processor Performance-Monitoring Counters (Contd.)**

| Event Num. | Mnemonic Event Name                         | Description                                                                                                     | Comments                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|------------|---------------------------------------------|-----------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 16H        | INSTRUCTIONS_EXECUTED                       | Number of instructions executed (up to two per clock).                                                          | Invocations of a fault handler are considered instructions. All hardware and software interrupts and exceptions will also cause the count to be incremented. Repeat prefixed string instructions will only increment this counter once despite the fact that the repeat loop executes the same instruction multiple times until the loop criteria is satisfied.<br><br>This applies to all the Repeat string instruction prefixes (i.e., REP, REPE, REPZ, REPNE, and REPNZ). This counter will also only increment once per each HLT instruction executed regardless of how many cycles the processor remains in the HALT state. |
| 17H        | INSTRUCTIONS_EXECUTED_V PIPE                | Number of instructions executed in the V_pipe. The event indicates the number of instructions that were paired. | This event is the same as the 16H event except it only counts the number of instructions actually executed in the V-pipe.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| 18H        | BUS_CYCLE_DURATION                          | Number of clocks while a bus cycle is in progress.<br><br>This event measures bus use.                          | The count includes HLDA, AHOLD, and BOFF# clocks.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| 19H        | WRITE_BUFFER_FULL_STALL_DURATION            | Number of clocks while the pipeline is stalled due to full write buffers.                                       | Full write buffers stall data memory read misses, data memory write misses, and data memory write hits to S-state lines. Stalls on I/O accesses are not included.                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| 1AH        | WAITING_FOR_DATA_MEMORY_READ_STALL_DURATION | Number of clocks while the pipeline is stalled while waiting for data memory reads.                             | Data TLB Miss processing is also included in the count. The pipeline stalls while a data memory read is in progress including attempts to read that are not bypassed while a line is being filled.                                                                                                                                                                                                                                                                                                                                                                                                                               |

**Table A-23. Events That Can Be Counted with Pentium Processor Performance-Monitoring Counters (Contd.)**

| Event Num. | Mnemonic Event Name                     | Description                                                                                                                                                            | Comments                                                                                                                                                                                                                                |
|------------|-----------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1BH        | STALL ON WRITE TO AN E- OR M-STATE LINE | Number of stalls on writes to E- or M-state lines.                                                                                                                     |                                                                                                                                                                                                                                         |
| 1CH        | LOCKED BUS CYCLE                        | Number of locked bus cycles that occur as the result of the LOCK prefix or LOCK instruction, page-table updates, and descriptor table updates.                         | Only the read portion of the locked read-modify-write is counted. Split locked cycles (SCYC active) count as two separate accesses. Cycles restarted due to BOFF# are not re-counted.                                                   |
| 1DH        | I/O READ OR WRITE CYCLE                 | Number of bus cycles directed to I/O space.                                                                                                                            | Misaligned I/O accesses will generate two bus cycles. Bus cycles restarted due to BOFF# are not re-counted.                                                                                                                             |
| 1EH        | NONCACHEABLE_MEMORY_READS               | Number of noncacheable instruction or data memory read bus cycles. The count includes read cycles caused by TLB misses, but does not include read cycles to I/O space. | Cycles restarted due to BOFF# are not re-counted.                                                                                                                                                                                       |
| 1FH        | PIPELINE_AGI_STALLS                     | Number of address generation interlock (AGI) stalls. An AGI occurring in both the U- and V- pipelines in the same clock signals this event twice.                      | An AGI occurs when the instruction in the execute stage of either of U- or V-pipelines is writing to either the index or base address register of an instruction in the D2 (address generation) stage of either the U- or V- pipelines. |
| 20H        | Reserved                                |                                                                                                                                                                        |                                                                                                                                                                                                                                         |
| 21H        | Reserved                                |                                                                                                                                                                        |                                                                                                                                                                                                                                         |

## PERFORMANCE-MONITORING EVENTS

**Table A-23. Events That Can Be Counted with Pentium Processor Performance-Monitoring Counters (Contd.)**

| Event Num. | Mnemonic Event Name              | Description                                     | Comments                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|------------|----------------------------------|-------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 22H        | FLOPS                            | Number of floating-point operations that occur. | <p>Number of floating-point adds, subtracts, multiplies, divides, remainders, and square roots are counted. The transcendental instructions consist of multiple adds and multiplies and will signal this event multiple times. Instructions generating the divide-by-zero, negative square root, special operand, or stack exceptions will not be counted.</p> <p>Instructions generating all other floating-point exceptions will be counted. The integer multiply instructions and other instructions which use the x87 FPU will be counted.</p> |
| 23H        | BREAKPOINT MATCH ON DR0 REGISTER | Number of matches on register DR0 breakpoint.   | <p>The counters is incremented regardless if the breakpoints are enabled or not. However, if breakpoints are not enabled, code breakpoint matches will not be checked for instructions executed in the V-pipe and will not cause this counter to be incremented. (They are checked on instruction executed in the U-pipe only when breakpoints are not enabled.)</p> <p>These events correspond to the signals driven on the BP[3:0] pins. Refer to Chapter 16, "Debugging, Profiling Branches and Time-Stamp Counter" for more information.</p>   |
| 24H        | BREAKPOINT MATCH ON DR1 REGISTER | Number of matches on register DR1 breakpoint.   | See comment for 23H event.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| 25H        | BREAKPOINT MATCH ON DR2 REGISTER | Number of matches on register DR2 breakpoint.   | See comment for 23H event.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

**Table A-23. Events That Can Be Counted with Pentium Processor Performance-Monitoring Counters (Contd.)**

| Event Num. | Mnemonic Event Name                          | Description                                                                                                                                                          | Comments                                                                                                                                                                                                                                                                                                                                     |
|------------|----------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 26H        | BREAKPOINT MATCH ON DR3 REGISTER             | Number of matches on register DR3 breakpoint.                                                                                                                        | See comment for 23H event.                                                                                                                                                                                                                                                                                                                   |
| 27H        | HARDWARE INTERRUPTS                          | Number of taken INTR and NMI interrupts.                                                                                                                             |                                                                                                                                                                                                                                                                                                                                              |
| 28H        | DATA_READ_OR_WRITE                           | Number of memory data reads and/or writes (internal data cache hit and miss combined).                                                                               | Split cycle reads and writes are counted individually. Data Memory Reads that are part of TLB miss processing are not included. These events may occur at a maximum of two per clock. I/O is not included.                                                                                                                                   |
| 29H        | DATA_READ_MISS OR_WRITE MISS                 | Number of memory read and/or write accesses that miss the internal data cache, whether or not the access is cacheable or noncacheable.                               | Additional reads to the same cache line after the first BRDY# of the burst line fill is returned but before the final (fourth) BRDY# has been returned, will not cause the counter to be incremented additional times. Data accesses that are part of TLB miss processing are not included. Accesses directed to I/O space are not included. |
| 2AH        | BUS OWNERSHIP_LATENCY (Counter 0)            | The time from LRM bus ownership request to bus ownership granted (that is, the time from the earlier of a PBREQ (0), PHITM# or HITM# assertion to a PBGNT assertion) | The ratio of the 2AH events counted on counter 0 and counter 1 is the average stall time due to bus ownership conflict.                                                                                                                                                                                                                      |
| 2AH        | BUS OWNERSHIP TRANSFERS (Counter 1)          | The number of bus ownership transfers (that is, the number of PBREQ (0) assertions                                                                                   | The ratio of the 2AH events counted on counter 0 and counter 1 is the average stall time due to bus ownership conflict.                                                                                                                                                                                                                      |
| 2BH        | MMX_INSTRUCTIONS_EXECUTED_U-PIPE (Counter 0) | Number of MMX instructions executed in the U-pipe                                                                                                                    |                                                                                                                                                                                                                                                                                                                                              |

## PERFORMANCE-MONITORING EVENTS

**Table A-23. Events That Can Be Counted with Pentium Processor Performance-Monitoring Counters (Contd.)**

| Event Num. | Mnemonic Event Name                                     | Description                                                                                                                                                                             | Comments                                                                                                                                                                                                                                                             |
|------------|---------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 2BH        | MMX_INSTRUCTIONS_EXECUTED_V-PIPE (Counter 1)            | Number of MMX instructions executed in the V-pipe                                                                                                                                       |                                                                                                                                                                                                                                                                      |
| 2CH        | CACHE_M-STATE_LINE_SHARING (Counter 0)                  | Number of times a processor identified a hit to a modified line due to a memory access in the other processor (PHITM (0))                                                               | If the average memory latencies of the system are known, this event enables the user to count the Write Backs on PHITM(0) penalty and the Latency on Hit Modified(l) penalty.                                                                                        |
| 2CH        | CACHE_LINE_SHARING (Counter 1)                          | Number of shared data lines in the L1 cache (PHIT (0))                                                                                                                                  |                                                                                                                                                                                                                                                                      |
| 2DH        | EMMS_INSTRUCTIONS_EXECUTED (Counter 0)                  | Number of EMMS instructions executed                                                                                                                                                    |                                                                                                                                                                                                                                                                      |
| 2DH        | TRANSITIONS_BETWEEN_MMX_AND_FP_INSTRUCTIONS (Counter 1) | Number of transitions between MMX and floating-point instructions or vice versa<br><br>An even count indicates the processor is in MMX state. an odd count indicates it is in FP state. | This event counts the first floating-point instruction following an MMX instruction or first MMX instruction following a floating-point instruction.<br><br>The count may be used to estimate the penalty in transitions between floating-point state and MMX state. |
| 2EH        | BUS_UTILIZATION_DUE_TO_PROCESSOR_ACTIVITY (Counter 0)   | Number of clocks the bus is busy due to the processor's own activity (the bus activity that is caused by the processor)                                                                 |                                                                                                                                                                                                                                                                      |
| 2EH        | WRITES_TO_NONCACHEABLE_MEMORY (Counter 1)               | Number of write accesses to noncacheable memory                                                                                                                                         | The count includes write cycles caused by TLB misses and I/O write cycles.<br><br>Cycles restarted due to BOFF# are not re-counted.                                                                                                                                  |

**Table A-23. Events That Can Be Counted with Pentium Processor Performance-Monitoring Counters (Contd.)**

| Event Num. | Mnemonic Event Name                             | Description                                                                                                    | Comments                                                                                                                                                                                                                                                                                                                   |
|------------|-------------------------------------------------|----------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 2FH        | SATURATING_MMX_INSTRUCTIONS_EXECUTED(Counter 0) | Number of saturating MMX instructions executed, independently of whether they actually saturated.              |                                                                                                                                                                                                                                                                                                                            |
| 2FH        | SATURATIONS_PERFORMED(Counter 1)                | Number of MMX instructions that used saturating arithmetic when at least one of its results actually saturated | If an MMX instruction operating on 4 doublewords saturated in three out of the four results, the counter will be incremented by one only.                                                                                                                                                                                  |
| 30H        | NUMBER_OF_CYCLES_NOT_IN_HALT_STATE(Counter 0)   | Number of cycles the processor is not idle due to HLT instruction                                              | This event will enable the user to calculate "net CPI". Note that during the time that the processor is executing the HLT instruction, the Time-Stamp Counter is not disabled. Since this event is controlled by the Counter Controls CCO, CC1 it can be used to calculate the CPI at CPL=3, which the TSC cannot provide. |
| 30H        | DATA_CACHE_TLB_MISS_STALL_DURATION(Counter 1)   | Number of clocks the pipeline is stalled due to a data cache translation look-aside buffer (TLB) miss          |                                                                                                                                                                                                                                                                                                                            |
| 31H        | MMX_INSTRUCTION_DATA_READS(Counter 0)           | Number of MMX instruction data reads                                                                           |                                                                                                                                                                                                                                                                                                                            |
| 31H        | MMX_INSTRUCTION_DATA_READ_MISSES(Counter 1)     | Number of MMX instruction data read misses                                                                     |                                                                                                                                                                                                                                                                                                                            |
| 32H        | FLOATING_POINT_STALLS_DURATION(Counter 0)       | Number of clocks while pipe is stalled due to a floating-point freeze                                          |                                                                                                                                                                                                                                                                                                                            |

## PERFORMANCE-MONITORING EVENTS

**Table A-23. Events That Can Be Counted with Pentium Processor Performance-Monitoring Counters (Contd.)**

| Event Num. | Mnemonic Event Name                                        | Description                                                                                                     | Comments                                                                                                                                                                                                                                                                                                                                                            |
|------------|------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 32H        | TAKEN_BRANCHES (Counter 1)                                 | Number of taken branches                                                                                        |                                                                                                                                                                                                                                                                                                                                                                     |
| 33H        | D1_STARVATION_AND_FIFO_IS_EMPTY (Counter 0)                | Number of times D1 stage cannot issue ANY instructions since the FIFO buffer is empty                           | The D1 stage can issue 0, 1, or 2 instructions per clock if those are available in an instructions FIFO buffer.                                                                                                                                                                                                                                                     |
| 33H        | D1_STARVATION_AND_ONLY_ONE_INSTRUCTION_IN_FIFO (Counter 1) | Number of times the D1 stage issues a single instruction (since the FIFO buffer had just one instruction ready) | The D1 stage can issue 0, 1, or 2 instructions per clock if those are available in an instructions FIFO buffer.<br><br>When combined with the previously defined events, Instruction Executed (16H) and Instruction Executed in the V-pipe (17H), this event enables the user to calculate the numbers of time pairing rules prevented issuing of two instructions. |
| 34H        | MMX_INSTRUCTION_DATA_WRITES (Counter 0)                    | Number of data writes caused by MMX instructions                                                                |                                                                                                                                                                                                                                                                                                                                                                     |
| 34H        | MMX_INSTRUCTION_DATA_WRITE_MISSES (Counter 1)              | Number of data write misses caused by MMX instructions                                                          |                                                                                                                                                                                                                                                                                                                                                                     |

**Table A-23. Events That Can Be Counted with Pentium Processor Performance-Monitoring Counters (Contd.)**

| Event Num. | Mnemonic Event Name                                                               | Description                                                                                               | Comments                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|------------|-----------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 35H        | PIPELINE_FLUSHES_DUE_TO_WRONG_BRANCH_PREDICTIONS (Counter 0)                      | Number of pipeline flushes due to wrong branch predictions resolved in either the E-stage or the WB-stage | The count includes any pipeline flush due to a branch that the pipeline did not follow correctly. It includes cases where a branch was not in the BTB, cases where a branch was in the BTB but was mispredicted, and cases where a branch was correctly predicted but to the wrong address. Branches are resolved in either the Execute stage (E-stage) or the Writeback stage (WB-stage). In the later case, the misprediction penalty is larger by one clock. The difference between the 35H event count in counter 0 and counter 1 is the number of E-stage resolved branches. |
| 35H        | PIPELINE_FLUSHES_DUE_TO_WRONG_BRANCH_PREDICTIONS_RESOLVED_IN_WB-STAGE (Counter 1) | Number of pipeline flushes due to wrong branch predictions resolved in the WB-stage                       | See note for event 35H (Counter 0).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| 36H        | MISALIGNED_DATA_MEMORY_REFERENCE_ON_MMX_INSTRUCTIONS (Counter 0)                  | Number of misaligned data memory references when executing MMX instructions                               |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| 36H        | PIPELINE_INSTALL_FOR_MMX_INSTRUCTION_DATA_MEMORY_READS (Counter 1)                | Number clocks during pipeline stalls caused by waits for MMX instruction data memory reads                | T3:                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

## PERFORMANCE-MONITORING EVENTS

**Table A-23. Events That Can Be Counted with Pentium Processor Performance-Monitoring Counters (Contd.)**

| Event Num. | Mnemonic Event Name                                                | Description                                                                                                                                                   | Comments                                                                                                                                                                                                                                                                                                      |
|------------|--------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 37H        | MISPREDICTED_OR_UNPREDICTED_RETURNS<br>(Counter 1)                 | Number of returns predicted incorrectly or not predicted at all                                                                                               | The count is the difference between the total number of executed returns and the number of returns that were correctly predicted. Only RET instructions are counted (for example, IRET instructions are not counted).                                                                                         |
| 37H        | PREDICTED_RETURNS<br>(Counter 1)                                   | Number of predicted returns (whether they are predicted correctly and incorrectly)                                                                            | Only RET instructions are counted (for example, IRET instructions are not counted).                                                                                                                                                                                                                           |
| 38H        | MMX_MULTIPLY_UNIT_INTERLOCK<br>(Counter 0)                         | Number of clocks the pipe is stalled since the destination of previous MMX multiply instruction is not ready yet                                              | The counter will not be incremented if there is another cause for a stall. For each occurrence of a multiply interlock, this event will be counted twice (if the stalled instruction comes on the next clock after the multiply) or by once (if the stalled instruction comes two clocks after the multiply). |
| 38H        | MOVD/MOVQ_STORE_STALL_DUE_TO_PREVIOUS_MMX_OPERATION<br>(Counter 1) | Number of clocks a MOVD/MOVQ instruction store is stalled in D2 stage due to a previous MMX operation with a destination to be used in the store instruction. |                                                                                                                                                                                                                                                                                                               |
| 39H        | RETURNS<br>(Counter 0)                                             | Number of returns executed.                                                                                                                                   | Only RET instructions are counted; IRET instructions are not counted. Any exception taken on a RET instruction and any interrupt recognized by the processor on the instruction boundary prior to the execution of the RET instruction will also cause this counter to be incremented.                        |
| 39H        | Reserved                                                           |                                                                                                                                                               |                                                                                                                                                                                                                                                                                                               |

**Table A-23. Events That Can Be Counted with Pentium Processor Performance-Monitoring Counters (Contd.)**

| Event Num. | Mnemonic Event Name                                                              | Description                                                                                               | Comments                                                                  |
|------------|----------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------|
| 3AH        | BTB_FALSE_ENTRIES<br>(Counter 0)                                                 | Number of false entries in the Branch Target Buffer                                                       | False entries are causes for misprediction other than a wrong prediction. |
| 3AH        | BTB_MISS_PREDICTION_ON_NOT-TAKEN_BRANCH<br>(Counter 1)                           | Number of times the BTB predicted a not-taken branch as taken                                             |                                                                           |
| 3BH        | FULL_WRITE_BUFFER_STALL_DURATION WHILE_EXECUTING_MMX_INSTRUCTIONS<br>(Counter 0) | Number of clocks while the pipeline is stalled due to full write buffers while executing MMX instructions |                                                                           |
| 3BH        | STALL_ON_MMX_INSTRUCTION_WRITE_TO_E_OR_M-STATE_LINE<br>(Counter 1)               | Number of clocks during stalls on MMX instructions writing to E- or M-state lines                         |                                                                           |

## PERFORMANCE-MONITORING EVENTS

## APPENDIX B MODEL-SPECIFIC REGISTERS (MSRs)

This appendix lists MSRs provided in Intel® Core™ 2 processor family, Intel® Atom™, Intel® Core™ Duo, Intel® Core™ Solo, Pentium® 4 and Intel® Xeon® processors, P6 family processors, and Pentium® processors in Tables B-13, B-18, and B-19, respectively. All MSRs listed can be read with the RDMSR and written with the WRMSR instructions.

Register addresses are given in both hexadecimal and decimal. The register name is the mnemonic register name and the bit description describes individual bits in registers.
